

Do board connections between product market peers impede competition? *

Radhakrishnan Gopalan Renping Li Alminas Žaldokas

February 2024

Abstract

After a new direct board connection is formed to a product market peer, a firm's gross margin increases by 0.8 p.p. Gross margin also rises by 0.4 p.p. after a connection is formed to a peer indirectly through a third intermediate firm. Using barcode-level data, we further show that new board connections are related to higher prices of consumer goods and a greater tendency to reduce head-on competition. Such board connections have positive profitability spillovers on the closest rivals, and the effects are stronger when the newly connected peers share corporate customers, have more similar business descriptions, or are closer geographically.

Keywords: board of directors, interlocking directorships, product market coordination, antitrust

*“For too long, our Section 8 enforcement has essentially been limited to our merger review process. We are ramping up efforts to identify violations across the broader economy, and we will not hesitate to bring Section 8 cases to break up interlocking directorates.”*¹

*(The DOJ’s recent crackdown on interlocking boards is) “probably the most effective way of deconcentrating the United States economy today.”*²

- Jonathan Kanter

Board connections can enable the flow of information between firms and help coordinate anti-competitive behavior. Recognizing this, Section 8 of the Clayton Antitrust Act of 1914 (the Clayton Act) prohibits firms with substantial overlap in their activities from sharing directors. However, product-market director interlocks might be more prevalent than expected. One possible reason is that in a rapidly changing environment of business strategies and product lines, such as in the technology sector, it is challenging to determine which firms compete with one another at a given point in time. Moreover, information can flow across competing firms not only through a directly shared common director but in general through the broader director network. Since directors routinely sit on multiple firm boards, firms can become linked through a director network via another firm.

Noting these challenges, the Biden Administration is ramping up efforts to upscale the enforcement of the Clayton Act.³ While a heated discussion revolving around interlocking directorships among competing firms is drawing public attention, the evidence on the anti-competitive effects of these connections is rare. In this paper we map the director networks of firms that compete in the product market to explore their anti-competitive role, and find that the board connections between product market peers are not only common but are associated with higher firm profitability, increased product prices, and market division.

We define product market peer firms based on the Hoberg-Phillips industry classification (Hoberg and Phillips, 2010, 2016) and identify instances when such firms are closely linked

¹Opening Remarks at the 2022 Spring Enforcers Summit held by the Department of Justice (DOJ) and Federal Trade Commission (FTC).

²Remarks at the 2023 American Bar Association Antitrust Spring Meeting.

³Recently, the DOJ administered a series of investigations on interlocking directorships. On October 19, 2022, the DOJ shared that seven directors resigned from corporate board positions in response to concerns by the Antitrust Division that their roles violated the Clayton Act, followed by the resignation of five more directors on March 9, 2023 (Department of Justice, 2022, 2023). The FTC also raised its first case in 40 years that enforces Section 8 of the Clayton Act by barring interlocking directorship between two energy companies (Federal Trade Commission, 2023a).

through the director networks. We consider that two firms have a *direct* board connection if they share a director, and that two firms have an *indirect* board connection if they do not share any board members directly but at least one member of their respective boards serves on the board of a third firm. In the twenty-year period of 1999-2018, we identify 1,493 instances of new direct connections to a product market peer and 4,085 instances of new indirect connections to a product market peer. These 1,493 instances of direct board connections between firms that are potentially in the same product market space – at least according to the Hoberg-Phillips classification – indicate the possibility of imperfect enforcement of the Clayton Act restrictions on board connections between competing firms.

Our main analysis adopts a difference-in-differences model to study the relationship between new board connections between product market peers and newly connected firm profitability. For every firm that forms a new board connection (“treated” firm), we identify a control firm that is from the same year and the same industry as the treated firm and is the closest to the treated firm in terms of total assets, gross margin, and Tobin’s Q in the year before the new board appointment (“treatment” or “event”). We find that the set of treated and control firms are indistinguishable in terms of the matching co-variables in the year prior to treatment. The first difference in our model is between the treated and control firms while the second difference is between the time period before and after the treatment.

We capture firm profitability in different ways: the gross profit margin, the operating profit margin, and the return on assets (ROA). We find that firm profitability significantly increases in the three years after a firm forms a board connection to a product market peer. The increase happens both following a direct and following an indirect connection and is robust to how we measure profitability. Our estimates are economically significant. In the three years following an indirect connection to a product market peer, a firm’s gross margin, operating margin, and ROA increase by 0.4 p.p., 0.8 p.p., and 0.7 p.p., respectively. The estimates are even larger following a direct connection to a product market peer and, respectively, are 0.8 p.p., 1.4 p.p., and 0.9 p.p. We do not see any differential pre-existing trends in profitability between the treated and control firms.

Our interpretation that these board appointments are anti-competitive faces at least two concerns. First, the changes to the board of directors are likely endogenous to the firm’s

future prospects. For example, firms that anticipate an improvement in their performance could afford appointing a director who is a better expert in their industry and thus likely connected to another product market peer. Also, the directors of a firm with improving prospects could be more valued in the director labor market and thus more likely to be appointed to the boards of product market peers. Second, even if they were exogenous, board connections can also improve profitability by propagating governance practices that could enhance the internal efficiency of the firm (see, e.g., Bouwman (2011)).

We approach these concerns by designing tests that (a) focus on new connections that do not arise from the changes in the treated firm’s board and that (b) distinguish the interpretation of anti-competitive effects from the internal efficiency improvements. These tests also provide us with richer and more granular ways to interpret the mechanisms behind our baseline estimates.

First, we zoom into indirect connection events and isolate a particular subset of connections that are formed because of the changes in the boards of an intermediate firm or a product market peer but that are not related to the changes in the board of the focal firm, nor the new appointments of its present directors. That is, we look at the cases where the intermediate firm that already shares the director with the focal firm appoints a director from the peer firm, or the peer firm appoints the director from the intermediate firm. We deem these events more likely to be exogenous to the focal firm’s future prospects and still find a similar increase in its profitability.

Second, we study the consumer goods sector. Using the Nielsen Retail Scanner Data, which contains detailed information on store-specific barcode-level prices and revenues for over 2.7 million products by firms in our sample, we find evidence that board connections are related to coordinated product price movements and market division. Our empirical specifications make use of within-firm variations for firms that sell in multiple product categories and also control for within-product-category and within-geographic-area time trends. We find that after board connections are formed, the product prices of products in categories that overlap with a firm’s newly directly connected peer grow 0.22 p.p. faster per quarter than products of the same firm in categories that do not overlap with its connected peer. This translates into a 0.88 p.p. annualized difference. Indirect connections have smaller yet

statistically significant effects.

We also examine how these new board connections relate to market division, another type of coordination when firms adjust their product offerings to avoid direct competition (Belleflamme and Bloch, 2004; Sullivan, 2020; De Leverano, 2023). Based on the cosine similarity of the geographic distribution of sales between firm-pairs, we see that while similarity does not change after direct connections, firms grow more distant after indirect ones.

We interpret both the rise in price and the drop in similarity as evidence that board connections could enable anti-competitive practices. More importantly, these findings suggest differential coordination mechanisms for direct versus indirect connections. While the direct connections have much stronger effects on product market prices, the indirect ones are more associated with the tendency to differentiate their sales portfolios and avoid head-on rivalry.

Third, we implement a series of cross-sectional tests for our main results. We sort events based on a range of characteristics and then employ triple-differences models. We first find that the introduction of Corporate Opportunity Waivers (COWs) in some states, which reduced the legal risks of a director sitting on multiple boards, increases both the frequency and profit-enhancing effects of board connections. We also show that connections to peers that share major corporate customers, have more similar businesses according to the cosine similarity score of firms' product descriptions, or are closer geographically have stronger effects on firm profitability. The effects are also stronger in industries where the potential benefits of coordination are greater.

Fourth, we investigate the spillover effects of board connections to the closest common rivals of newly connected firms. Suppose board connections enable anti-competitive practices such as price-fixing. In such a case, we could expect that the closest rivals operating in the same industry are able to follow the so-called "umbrella pricing" and also raise prices (Bos and Harrington, 2010). However, if board connections enhance firms' internal efficiency, those rivals not involved in the newly formed network will be put at a relative disadvantage and could see their profitability worsening when faced with more efficient rivals. We find evidence supportive of the former, which is more consistent with the anti-competitive explanation.

Fifth, we document how board connections relate to detected collusion cases. We find that while two directly connected firms have a probability of 0.058% of having an active

detected collusion case and it is 0.061% for a firm-pair with one degree of separation, this probability becomes 0.017% for the firm-pairs with two degrees of separation and 0.004% for the firm-pairs with three degrees of separation. This strong associative relationship also suggests that director networks can play a role in facilitating anti-competitive practices.

We conduct a number of robustness tests, including a placebo test showing that non-peer board connections do not display such a concurrent increase in profitability. In addition, we discuss that board overlaps might be associated with common ownership (Azar, 2022). We indeed document that those firms experiencing new board connections are more likely to have a concurrent increase in within-industry common ownership than the control firms. However, we also show that common ownership does not fully explain the effects that board connections have on firm performance.

This paper provides large-sample evidence that board connections between product market peers are related to better overall operating performance, higher product prices, and a greater tendency to avoid head-on competition, which are consistent with the anticompetitive effects. The contemporaneous literature has been investigating various aspects of the board connections between product market peers. Geng et al. (2023) found that reducing legal risk of sharing information outside of the board of directors increases the frequency of board overlap, which is then associated with higher sales revenue and profit margin. Barone et al. (2022) showed that restricting interlocking directorships among banks reduces the interest rates of loans extended by previously interlocked banks. Cabezon and Hoberg (2024) discussed the intellectual property leakage between product market peers connected through the boards of directors. Compared to this literature, we look at a broader firm sample and document the pervasiveness of both direct and, importantly, indirect board connections between firms in the same product space and their positive effects on connected firms' profitability. Moreover, the multi-product data allow us to identify both price and non-price effects of board connections in the product markets.

The paper also contributes to the literature on firm conduct that facilitates anti-competitive practices. Recent literature has extensively looked at whether sharing common investors between the firms contributes to higher product prices (see, e.g., Azar et al. (2018); Antón et al. (2023); Aslan (2023)). Tacit coordination can also be achieved with financial disclo-

sure (Bourveau et al., 2020) or executive compensation Ha et al. (2024). We highlight board connections as one form how tacit coordination in product markets can be made easier.

In addition, this paper speaks to our understanding of the dual role of directors as both advisors and monitors in a firm (Güner et al., 2008; Adams and Ferreira, 2009; Duchin et al., 2010; Dass et al., 2013; Drobetz et al., 2018; Gopalan et al., 2021) and focuses on how such roles change when the directors can be used to coordinate product market behavior between the competing firms. Relatedly, Campello et al. (2017) showed that independent directors suffer personal costs from cartel prosecutions and they take actions to mitigate those costs.

Finally, we add to the literature on social networks and, in particular, the network of directors. At the firm level, prior research has found that the network of directors enhances firm value (Bakke et al., 2024), affects investment decisions (Fracassi and Tate, 2012; Chuluun et al., 2017), disclosure (Intintoli et al., 2018), and governance policies (Coles et al., 2020; Renneboog and Zhao, 2014; Bouwman, 2011), and is associated with better merger outcomes (Cai and Sevilir, 2012; El-Khatib et al., 2015), more intellectual property leakage (Cabezon and Hoberg, 2024), and greater stock price synchronicity (Khanna and Thomas, 2009). This network has also been shown to influence director-level outcomes. Goergen et al. (2019) provided evidence that more connected directors make more profitable insider trades, which corroborates the existence of information exchange via this network, and Intintoli et al. (2018) showed that more connected directors have better career prospects. We restrict our attention to connections with competitors and posit that this economically important class of connections is associated with better future firm profitability. We also provide a novel reduced-form identification strategy of indirect connection formation, which bypasses the concern that the formation of new connections could correlate with unobservable future prospects and allows us to identify their treatment effects.

1 Hypothesis Development

Successful coordination among competitors yields monopolistic profits, which can be divided among these competitors and thus can exceed their respective profits under oligopolistic competition. Among many ways, such coordination can for example come in the form of

price-fixing schemes, in which two firms competing in the same market agree to fix the price at a high level, or market allocation, in which competing firms agree to each serve a separate product category, geographic area, or demographic group.

Although the benefits might be substantial to the shareholders of participating firms, successful coordination is hard to achieve for several reasons. First, an equilibrium with successful tacit coordination might be challenging to sustain, as it can be optimal for the participating firms to deviate and engage in predatory behaviors, such as cutting prices or entering into their competitor's market segment (Wiseman, 2017). Second, communication channels among competing firms might be imperfect, so crucial competition-sensitive information such as distribution, marketing, and pricing schemes might not reach or be trusted by the rival decision-makers (Kandori and Matsushima, 1998; Genesove and Mullin, 2001; Awaya and Krishna, 2016). Third, explicit collusion is illegal and suspected colluding firms might face legal actions (Department of Justice and Federal Trade Commission, 2000).

We argue that board connections are one way to facilitate anti-competitive practices by alleviating the aforementioned hurdles to successful coordination. Board connections might give opportunities for direct communication between the competing firms about their product market strategies or labor and supply chain policies. Moreover, the professional and personal interactions between directors can help build trust among competing firms and make deviations from coordination less likely to occur. In this sense, board connections can be considered as a kind of relational contract as in Baker et al. (2002). Also, even the interactions among directors of competing firms on the boards of other unrelated firms could facilitate coordination. Observing the rival firms' director voting behavior on third boards could improve understanding of how decisions in the rival firms are made, which could then be internalized into more informed reaction functions for firms' strategic interactions.⁴

While the Clayton Act prohibits interlocking directorships among competing firms, regulators seldomly proactively search for violations and its enforcement has been limited to the cases of merger reviews.⁵ Moreover, it is the burden of regulators to consider whether

⁴Directors might also be better aware of other firms' financial policies, and influence them to be less aggressive, in turn making the strategic competition less fierce.

⁵The Clayton Act bans interlocking directorships if the competitive sales are more than \$4,525,700, more than 2% of total sales for both firms, *and* more than 4% of total sales for either firm. Competitive sales are defined as the gross revenues for all products and services sold by one firm in competition with the other

two firms share the same product market and can be perceived to be competing. In today’s overlapping product markets, product market definition is often under debate.⁶

Nonetheless, there are several reasons why board connections to product market peers might not lead to more coordination. First, one may argue that the role of directors is to monitor the behavior of managers and does not entail interfering with firms’ product market strategies. Second, when the potential gains from coordination are large, firms might have found alternative vehicles to facilitate and sustain coordination, so the treatment of board connections would have null effects. Third, board connections might be correlated with busier directors simultaneously sitting on many boards, which might hinder directors’ ability to perform their duty in a single firm (Core et al., 1999; Fich and Shivdasani, 2006). Hence, it remains an empirical question whether board connections to product market peers lead to easier coordination in product markets and thus superior profitability.

2 Data and Sample Description

2.1 Data

We primarily draw our data from three sources: Compustat, BoardEx, and the 10-K Text-based Network Industry Classifications (TNIC) in the Hoberg-Phillips Data Library.

We put the following restrictions to construct the sample from the set of firms in the intersection of Compustat and BoardEx: (1) the firm is not in the financial industry or the utilities industry (SIC between 6000 and 6999, or between 4900 and 4999); (2) the firm-year has inflation-adjusted total assets above \$10 million and sales above \$4 million in 2018 dollars; (3) the gross margin and operating margin for the firm-year are both above -50%.

firm (Federal Trade Commission, 2023b). In practice, competitive sales are usually analyzed and determined on a case-by-case basis by industry experts.

⁶As an example, in its response to the inquiry of the United Kingdom’s Competition Market Authority, Facebook said that it saw its market share as the “time captured by Facebook as a percentage of total user time spent on the Internet, including social media, dating, news, and search platforms.” Similarly, Amazon (2020) reported that it “accounts for less than 1% of the \$25 trillion global retail market and less than 4% of retail in the US”, suggesting that it defines its relevant market as not only online but also offline retail markets. In fact, when the Antitrust Subcommittee of the U.S. House of Representatives requested Amazon for “a list of the Company’s top ten competitors,” Amazon identified 1,700 companies, including “a discount surgical supply distributor and a beef jerky company.”

To construct the network of directors, we start from the Individual Profile Employment dataset provided by BoardEx and we use entries where the type of employment is a board position. From this raw data, we construct annual network snapshots, with the nodes as the firms and the edges as the pairwise direct connections (i.e., interlocking directorships).

We then find board connections between firms that are product market peers based on the Hoberg-Phillips classification that is calibrated to be as fine as the SIC-3 industries (Hoberg and Phillips, 2010, 2016). In particular, firm’s competitors are determined by calculating the textual similarity score of the firm’s 10-K product descriptions with other publicly listed firms and retaining those to which the similarity score is above a certain threshold.

Our main variables are defined as follows. We define assets as the natural logarithm of the firm’s total assets in millions of dollars, gross margin as the ratio of gross profit to sales, operating margin as the ratio of operating income before depreciation and amortization to sales, ROA as the ratio of operating income before depreciation and amortization to total assets, sales growth as the percentage change of sales relative to the prior year, and Tobin’s Q as the ratio of the market value of equity plus book value of debt over total assets.⁷ All financial and accounting variables are winsorized at the 1% and 99% percentiles.

2.2 New board connections

Our main empirical exercise is an event study of instances when a firm forms a new board connection to a product market peer. We focus on both direct and indirect board connections between product market peers. We define that two firms have a *direct* board connection if they share a director, and we define that two firms have an *indirect* board connection if they do not share any board members directly but at least one member of their respective boards serves on the board of a third intermediate firm. We expect that forming a new direct board connection to a product market peer will correspond to a stronger effect on the firm profitability than forming an indirect one.

We define “treated” firms to be those firms that form a new board connection with a product market peer. Our treated sample then consists of all firms that form a new direct or indirect board connection with a product market peer during the period 1999-2018. We study

⁷Please see Internet Appendix Table A1 for the definitions of all variables we use in our analysis.

these firms for the seven-year period around the year when they form the new connection. When identifying these instances of newly formed board connections, we ensure that the firm does not have any prior indirect or direct board connection with its newly connected peers. We further ensure that in the instances of forming an indirect connection the firm does not concurrently form a direct connection with any of its peers.

We study how the firm profitability changes following the formation of the new board connection. To control for general industry trends in the outcome variables, we match each treated firm to a control firm that is from the same industry and has similar firm characteristics in the year before treatment. More specifically, for each treated firm-year, we look for one control firm-year, and we match with replacement. The matching takes the following steps. First, following Fracassi and Tate (2012), we require that the control firm is in the same Fama-French 17 industry as the treated firm, and the control firm itself is not treated in the event year. Second, we look for candidate control firms in the same quantiles of assets, gross margin, and Tobin’s Q and rank them by their Mahalanobis distance to the treated firm based on these three characteristics one year prior to the treatment. Finally, we retain the one candidate control firm with the smallest Mahalanobis distance to the treated firm. That forms each cohort of treated and control firms.

Our final sample comprises of a stacked set of these cohorts of treated and control firms for the treatment year, the three-year period before, and the three-year period after treatment, i.e., from year -3 to year +3 where year 0 refers to the treatment year.

2.3 Sample description

Our sample consists of 1,493 events of new direct connections to product market peers, and 4,085 events of new indirect connections to product market peers via an intermediate firm.⁸ Table 1 reports the distribution of the treated firms’ Fama-French 48 industries. The five industries with the most newly formed connections are Business Services (accounting

⁸Unconditional on being product market peers, board connections are quite prevalent in our sample. Over our sample period, we observe 57,809 new board connections formed between product and non-product market peers, of which 56.8% involve direct connections. A firm is on average directly connected to 4.4 firms and indirectly connected to 25.0 firms. In Section 5.1, we show that connections to a non-peer firm are not associated with increases in profitability.

for 20.6% of all events), Electronic Equipment (13.0%), Pharmaceutical Products (12.3%), Medical Equipment (8.5%), and Computers (7.7%).⁹

Table 2 reports the summary statistics for the treated and control firms in the year prior to the treatment (i.e., the year for which firm characteristics are used in the matching procedure) and also for all firms in Compustat. The data show that board connections to peers tend to occur in firms that are larger, have higher gross margin and Tobin’s Q, and faster sales growth. Consistent with Geng et al. (2023), such connections are also more likely among research and development (R&D) intensive firms. The operating margin in treated firms, however, are lower than average as these firms also have higher selling, general, and administrative (SG&A) expenses.¹⁰ Table 2 also shows that the treated and control firms are balanced in terms of the variables used in matching. The control firms are also similar to the treated firms in terms of almost all other co-variates not used in the matching.¹¹

In Table 3, we report the cumulative abnormal returns (CARs) in the days around the announcement of director appointments that trigger board connections to peers. We obtain the announcement dates from the Director and Officer Changes dataset provided by Audit Analytics. We calculate the CARs using the market model and a seven-day window centered around the announcement dates and report the means in column (1). We find that the average CAR after a firm announces the appointment of a director who cross-sits on the board of a peer firm is 0.83%. When a director cross-sits on an intermediate firm that is connected to a peer, the average CAR is 0.73%. In column (2), we report the CARs with the abnormal return calculated as the firm return minus the market return and find similar effects. These announcement returns are statistically significant and are much larger than the CARs around the announcement of non-interlocked appointments, suggesting that the

⁹Internet Appendix Figure A1 shows that new board connections are spread out through our sample period. 51.8% (69.1%) of the new direct (indirect) connections last for less than 4 years, 38.0% (27.1%) last for 4 to 8 years, while 10.2% (3.8%) last for longer than 8 years.

¹⁰We also compare how directors involved in these new connections differ from an average director in the treated firms. Internet Appendix Table A2 shows that, while those connected directors cross-sit on more boards and are more likely to be non-executive directors, their length of professional experience and educational level do not differ from that of an average director.

¹¹As we discuss in Section 3.2, the outcome variables do not show differential pre-trends between treated and control firms, which makes it unlikely that any residual unbalancedness in firm characteristics is driving our main results. Nevertheless, in the robustness tests reported in Section 5.4.3, we expand the list of matching co-variates and repeat our analysis. The baseline estimates are robust.

market reacts positively to the appointments under study.

In Figure 1, we compare the product market similarity of newly connected firms to that of all firm-pairs in a Hoberg-Phillips industry. Panel A studies direct connections and Panel B studies indirect connections. In both Panels, the solid green line plots the distribution of the cosine similarity of only the newly connected firm-pairs while the dashed orange line plots the distribution of the cosine similarity of all firm-pairs in a Hoberg-Phillips industry. We find that not only does the green line lie to the right of the orange line but its peak is also to the right of the peak of the orange line. This observation highlights that the newly connected firm-pairs tend to have a higher cosine similarity score than average Hoberg-Phillips industry peers, suggesting that businesses of the newly connected firm-pairs appear more similar as compared to average Hoberg-Phillips industry peers.

Table 4 reports the probability that the newly connected firms are in the same SIC or GICS industry. We also compare it to the probability that any Hoberg-Phillips industry peers are in the same SIC or GICS industry. This comparison indicates that the newly connected pairs of firms are more likely to be in the same SIC and GICS industry as compared to an average pair of product market peers and this holds for both direct and indirect connections. If anything, the fractions are even slightly larger for the indirect connections.

In sum, the evidence in both Figure 1 and Table 4 indicates that the new board connections occur between peer firms that are closer in the product space than the average Hoberg-Phillips product market peers.

3 Main Findings

3.1 Baseline effects

We study the impact of new board connections to product market peers on firm performance. To do this, we estimate a difference-in-differences model for our sample of treated and control firms. The first difference is taken between the time period before and after the event while the second difference is between the treated and control firms. Our empirical model is then:

$$\begin{aligned}
Y_{i,j,c,t} &= \alpha_1 \times Post_{c,t} + \alpha_2 \times DirectTreated_{i,c} + \alpha_3 \times IndirectTreated_{i,c} & (1) \\
&+ \beta_1 \times DirectTreated_{i,c} \times Post_{c,t} + \beta_2 \times IndirectTreated_{i,c} \times Post_{c,t} \\
&+ \theta_i + \theta_{j,t} + e_{i,j,c,t},
\end{aligned}$$

where i is the index for each firm, j is the index for each industry, c is the index for each cohort which consists of all observations of a treated firm and its matched control, and t is the index for each calendar year. $Y_{i,j,c,t}$ is one of our outcome variables: gross margin, operating margin, ROA, and sales growth. $Post_{c,t}$ is a dummy variable that takes a value of one for both treated and control firms for the years $\tau = 0, 1, 2,$ and $3,$ where $\tau = 0$ is the treatment year.¹² $DirectTreated_{i,c}$ is a dummy variable equal to one for the treated firms that experience a direct board connection to a product market peer while $IndirectTreated_{i,c}$ is a dummy variable equal to one for the treated firms that experience a new indirect board connection to a product market peer.¹³ The coefficients of interest are β_1 and β_2 that identify the change in the outcome variable for treated firms that respectively form a direct and an indirect board connection with a product market peer.

Our methodology of pooling cohorts of treated and control observations together and estimating a difference-in-differences model bears resemblance to Gormley and Matsa (2011), Deshpande and Li (2019), and Cengiz et al. (2019). We include two sets of fixed effects. First, we include firm fixed effects θ_i . Next, we include industry times calendar year fixed effects $\theta_{j,t}$ to control for wider industry-specific shocks, where industries are defined based on the Fama-French 48-industry classification.¹⁴ Throughout the paper, we cluster standard errors at the firm level to address serial correlation within a firm (Bertrand et al., 2004).

Panel A of Table 5 reports the findings from estimating the above regression. Columns (1)-(3) show that profitability uniformly increases in the three years after the firm forms a

¹² $Post_{c,t}$ is not absorbed by industry times calendar year fixed effects because treatments occur in different years for different cohorts.

¹³ $DirectTreated_{i,c}$ and $IndirectTreated_{i,c}$ are not absorbed by firm fixed effects since a firm might be treated with a new direct connection in one year and act as a control (or be treated with a new indirect connection) in another year.

¹⁴Section 5.5 shows that our results are unaffected if instead we use SIC-3 or FIC-200 classifications, where the latter is a version of the Hoberg-Phillips 10-K Text-based Fixed Industry Classifications.

new board connection with its product market peer. Also, the increase in profitability is greater following a direct connection as compared to that following an indirect connection, albeit the differences are weak in terms of the statistical significance.

Our estimates are economically meaningful. Column (1) suggests that the gross margin increases by 0.8 p.p. for a firm that forms a direct board connection with a product market peer. This is a 1.6% of the mean gross margin of the treated firms in the pre-treatment year. As reported in columns (2)-(3), our estimates of the increase in operating margin and ROA for a firm that forms a direct connection are 1.4 p.p. and 0.9 p.p., which constitute a much larger 11% and 10% of their respective mean values in the pre-treatment year.¹⁵

Consistent with firms limiting the expansion of their output while increasing their profitability following new board connections to their product market peers, in column (4), we report that the sales growth decreases by 2.3 p.p. after a firm forms a new direct connection with an industry peer. That said, we find no statistically significant effect on sales growth after a firm forms an indirect connection with a product market peer.

In Internet Appendix Table A3, we report the findings for some other outcome variables. We see an increase in the markups calculated using the production approach (De Loecker et al., 2020). Also, we find that the sales increase at a faster pace relative to the cost of goods sold, consistent with firms gaining market power. However, we find no evidence of reduced SG&A costs or increase in capital expenditure or R&D, or altered size of total assets.

Panel B of Table 5 shows that our main findings are robust to controlling for firm-cohort fixed effects as in Gormley and Matsa (2011) and separating events of direct and indirect connections. We defer more robustness tests to Section 5.

3.2 Dynamic specification

We next document the dynamics of the change in performance around new board connections. These tests should also allow us to study if there are any differential pre-existing trends in the outcome variables between the treated and control firms. To do this, we estimate the

¹⁵Gross margin is $\frac{\text{Sales}-\text{COGS}}{\text{Sales}} = 1 - \frac{\text{COGS}}{\text{Sales}}$ and operating margin is $\frac{\text{Sales}-\text{COGS}-\text{SG\&A}}{\text{Sales}} = 1 - \frac{\text{COGS}}{\text{Sales}} - \frac{\text{SG\&A}}{\text{Sales}}$, where COGS refers to costs of goods sold. Hence, due to an operating leverage effect, we would expect the increase in operating margin to be larger compared to gross margin if firms are gaining more pricing power and thus the sales expand at a faster rate than COGS and SG&A expenses, which is consistent with findings in Internet Appendix Table A3.

following regression within our sample:

$$\begin{aligned}
Y_{i,j,c,t} &= \alpha_1 \times DirectTreated_{i,c} + \alpha_2 \times IndirectTreated_{i,c} & (2) \\
&+ \sum_{s=-3}^{-2} \beta_s \times \mathbb{1}(\tau = s)_{c,t} + \sum_{s=0}^3 \beta_s \times \mathbb{1}(\tau = s)_{c,t} \\
&+ DirectTreated_{i,c} \times \left(\sum_{s=-3}^{-2} \gamma_s \times \mathbb{1}(\tau = s)_{c,t} + \sum_{s=0}^3 \gamma_s \times \mathbb{1}(\tau = s)_{c,t} \right) \\
&+ IndirectTreated_{i,c} \times \left(\sum_{s=-3}^{-2} \delta_s \times \mathbb{1}(\tau = s)_{c,t} + \sum_{s=0}^3 \delta_s \times \mathbb{1}(\tau = s)_{c,t} \right) \\
&+ \theta_i + \theta_{j,t} + e_{i,j,c,t}.
\end{aligned}$$

where t represents the calendar year and τ represents the year relative to the treatment. $\mathbb{1}(\tau = s)_{c,t}$ is a dummy variable that is equal to one if the observation is $-s$ years before the treatment (for $s = -3, -2$) or if the observation is s years after the treatment (for $s = 0, 1, 2, 3$). We omit the dummy variables for the year prior to the event, i.e., $\tau = -1$, which forms the baseline year. Thus all the effects we document are relative to this year. The estimates of γ_s and δ_s capture the difference in outcome variables between treated and control firms of year s relative to their difference in the baseline year.

We plot the coefficient estimates of γ_s and δ_s in Figure 2. Panels A1 and A2 report that there is no statistically significant difference in the gross margin between the treated and control firms in the years prior to the treatment for both direct and indirect connection events. This suggests the absence of pre-existing trends. Panel A1, which reports the results for the direct connections, shows that the gross margin of treated firms increases significantly starting from the second year following the formation of a new connection. Furthermore, the magnitude of the increase gets larger in the third year. This is consistent with the new director taking some time to get used to understanding the firm(s) and the board(s) before having an impact on performance. Panel A2 reports the results for the indirect connections, showing a similar pattern, albeit smaller in economic magnitude. We find similar patterns for operating margin and ROA, as reported in Panels B1-2 and C1-2.

3.3 Non-Focal-Firm Initiated Board Connection Changes

New board connections to a product market peer can arise either from changes to a firm’s board or from changes to the board of a connected firm. Indeed, new connections arising from changes to a firm’s board could be endogenous to the firm’s expected operating performance. For example, better-performing firms could afford appointing directors who are experts in their industry and thus also connected to product market peers. Also, the directors of a firm for which prospects are improving may be more valued in the director labor market and thus more likely to be appointed to the board of a product market peer.

We thus focus on new connections that are not related to the changes in the focal (i.e., treated) firm’s board, nor to the changes in other appointments of the focal firm’s directors. These connections arise from changes to a non-focal firm’s board. They are likely to be more exogenous to the future performance of the focal firm and this may enable us to better identify the causal effect of board connections to product market peers on firm performance.

In particular, to identify new board connections initiated due to changes on the board of a non-focal firm, we focus on indirect connections and look at the indirect board connections to product market peers that are initiated due to the changes in the board of either the intermediate firm or the product market peer. In these events, the focal firm is already directly connected with the intermediate firm prior to the treatment year. In the treatment year, the board changes in either the intermediate firm or the product market peer. That is, either when (1) the intermediate firm appoints a new director who is also on the board of a product market peer of the focal firm, or (2) a product market peer appoints a director who is also on the board of the intermediate firm. Consequently, the focal firm forms a new indirect connection to a product market peer via the intermediate firm. At the same time, we require that changes on the focal firm’s own board do not result in any direct or indirect connection between the focal firm and its product market peers. Thus, in these events, the new connection between the focal firm and its peer is not due to any changes to the board composition of the focal firm. To this extent we expect these connections to be more exogenous to the future prospects of the focal firm.¹⁶

Figure 3 illustrates an example, where Firm 1 is the focal firm and Firm 2 is a product

¹⁶We provide further details in Internet Appendix IA.2.

market peer of Firm 1. In the year prior to the event, Firm 1 and an intermediate firm, Firm 3, are directly connected through Director A who serves on the boards of both firms. Firm 1 does not have any direct or indirect connection to Firm 2. In the event year, Firm 2 forms a new direct connection with Firm 3 via Director B. This can be either due to Firm 2 newly appointing Director B, who is also on the board of Firm 3, or due to Director B, who has always been on the board of Firm 2, additionally taking on a board position in Firm 3. Either way, Firm 1 now gets to have an indirect connection with Firm 2, and this new connection is purely a result of changes in the composition of the board of directors of either the intermediate firm or a product market peer. It is not due to any change in the composition of Firm 1's board or due to changes in the directorships of any of its directors.

Out of the 4,085 events of indirect board connections in our overall sample, we find that 2,114 are initiated due to changes on the board of a firm other than the treated firm. Within this subsample, we estimate a regression (1) and present the results in Table 6.

Consistent with our prior evidence, column (1) shows that the gross margin of the treated firm increases by 0.7 p.p. in the three years following the initiation of non-focal-firm related indirect board connection to a product market peer. This estimate is larger than our baseline estimates based on all indirect board connections that showed a 0.4 p.p. increase in the gross margin, and suggests that, if anything, those board appointments that might be considered as more endogenous to the prospects of the treated firm appear to bias our baseline estimates downwards. Columns (2) and (3) imply that consistent with our baseline estimates our results are not sensitive to how we measure firm profitability.

The results are economically significant. The increase in gross margin, operating margin, and ROA are 1.4%, 8.5%, and 10% of the mean values for the treated firms in the year before treatment, respectively. Figure 4 presents the corresponding results of the dynamic model as in equation (2). Across the measures of profitability there is no pre-existing difference between the treated and control firms. We also show that the profitability significantly increases in the three years following the initiation of a new indirect board connection, independent of the measures employed.

While in Table 6 the new board connections that the treated firms experience are not due to any changes on their own boards, the remaining challenge to identification is that the

intermediate firm might be fundamentally correlated with the treated firm. Hence, certain unobservable factors might drive both board changes in the intermediate firm and also the future performance of the treated firm. This could be a particular concern if the treated and the intermediate firms have economic links. Indeed, we find that the intermediate firm is a Hoberg-Phillips peer of the treated firm for 752 non-focal-firm initiated events out of 2,114 in total. In Internet Appendix Table A4, we re-estimate the double-difference regressions excluding 752 board appointments when the intermediate firm is an industry peer. We find that our estimates are consistent when we restrict to non-focal-firm initiated cases where the intermediate firm is not a product market peer of the treated firm.

4 Anti-competitive Effects

Our findings are consistent with the interpretation that board connections to product market peers facilitate anti-competitive practices among competing firms.

That being said, board connections can also improve a firm’s profitability without anti-competitive coordination. For instance, Bouwman (2011) shows that good corporate governance practices can propagate across firms via the network of directors. The newly appointed board members might also have connections to regulators and thus be in high demand among industry peers (Emery and Faccio, 2023). If board connections facilitate the spread of corporate governance practices that enhance firms’ internal efficiency or new directors otherwise benefit the firms with their industry experience, they can have positive effects on firm profitability without any anti-competitive concerns.

We have already documented that the sales growth decreases after the new connections, and we do not find an increase in R&D expenditure or a decrease in SG&A costs. These findings are inconsistent with the efficiency-enhancing explanation. To further disentangle between the anti-competitive and the internal efficiency mechanisms, we first look for direct evidence of coordination using barcode-level data in the consumer goods sector. Second, we examine the effects of new board connections using a range of cross-sectional tests. Third, we investigate the spillover effects of new board connections to the closest rivals of those newly connected firms. Fourth, we look at the director deaths. Fifth, we link the board

network connections to the detected collusion cases.

4.1 Consumer goods sector

In order to corroborate the interpretation that our results relate to an anti-competitive mechanism, in this section we provide direct evidence on how board connections affect competition outcomes in one particular sector, the consumer goods. We make use of the Nielsen Retail Scanner Data, which contain prices and quantities from retail chains across the US.¹⁷ The price data are weekly and at a level as fine as each store and each individual Universal Product Code (UPC), which is a 12-digit barcode that identifies a unique traded item in stores. We adopt a similar event study methodology as our main test and look at how prices of products and the tendency to compete head-on change after producers form board connections to product market peers.

By narrowing down to the consumer goods sector, we can directly observe and measure firm’s actual behavior in its product markets. We can also sharpen the definition of product market competitors. In particular, we can define peers as firms that sell in the same “product module” or “product group” based on Nielsen Retail Scanner Data definitions.¹⁸

4.1.1 Sample construction and methodology

We start from the universe of Nielsen Retail Scanner Data in 2006-2020, which contain 6,087,712 distinct UPCs and record total annual sales of \$260.7 billion on average. We start by matching each UPC to a producer based on the UPC prefix data provided in the GS1 Company Database. We are able to assign producer information to 77.1% of all UPCs. Next, we match producers in GS1 Company Database to firms in BoardEx based on their name strings. We are able to match producers of 2,715,025 UPCs to BoardEx, which account for 44.6% of all UPCs and 63.4% of the total sales in the Nielsen Retail Scanner Data.¹⁹

¹⁷Prior research using this dataset has studied the product market impacts of common ownership (Aslan, 2023), private equity deals (Fracassi et al., 2022), taxation (Baker et al., 2023), and credit market disruption (Granja and Moreira, 2022; Kabir, 2022).

¹⁸Product data are organized in a hierarchical structure, with around 125 “product groups” and 1,100 “product modules”. E.g., the “product group” labelled as “Cheese” has 19 “product modules”, which include “Cheese-Natural-Mozzarella”, “Cheese-Natural-American Colby”, and “Cheese-Natural-American Cheddar”.

¹⁹The details of the matching procedure are provided in Internet Appendix IA.4

The relevant changes in board connections are defined in the same manner as in the tests for our baseline tests discussed in Section 2.2. Differently from our main tests for which we require a treated firm to be publicly listed and thus have financial information, in this analysis treated firms can be either publicly listed or privately held. Also, as we have firm outcomes at a higher frequency, we define board connection events at the quarterly level.

We build the relationship network based on all firm personnel but require the person connecting product market peers to be a director in at least one side of the connected firm-pair. When using a “product module” as the product category, which is the finest level in the data, we find 52 pairs of product market peers that form new direct board connections and 778 that form indirect ones. Using the higher level aggregation of a “product group” and thus a larger size of each “industry”, we instead find 74 pairs that form new direct board connections and 1,067 for indirect ones. We provide findings for both of these classifications.

We construct three groups of outcome variables that respectively capture the price, quantity, and firm pairs’ similarity in their sales portfolios. First, we estimate a price index following Aslan (2023). We define the set of products (UPCs) that firm i sells in product category c and 3-digit zip code area z and quarter t as its product portfolio and denote it as $U_{i,c,z,t}$. The share of revenue of each product u within the product portfolio is $w_{u,z,t}$, which sums up to one for a product portfolio, that is, $\sum_{u \in U_{i,c,z,t}} w_{u,z,t} = 1$. We define the average dollar price of product u in area z in quarter t to be $p_{u,z,t}$. The price index $P_{i,c,z,t}$ of firm i in product category c and area z and quarter t is then:

$$P_{i,c,z,t} = \sum_{u \in U_{i,c,z,t-1}} w_{u,z,t-1} \times (p_{u,z,t}/p_{u,z,t-1} - 1). \quad (3)$$

$P_{i,c,z,t}$ thus reflects the weighted average of firm i ’s UPC price changes in a category c in area z in quarter t , based on the firm i ’s UPC shares in category c . We exclude a UPC if the unit price in the current quarter is below 33% or above 300% of the prior quarter. We also exclude an observation $P_{i,c,z,t}$ if the total sales are below \$5,000 (\$10,000) or the market share is below 5% (1%) for firm i in product module (group) c and area z in the current quarter t or the prior quarter $t-1$ as these cases are unlikely to have sufficient market power.

Second, to capture the quantity effects of board connections, we construct a unit index.

We denote the units of product u sold in area z in quarter t to be $q_{u,z,t}$. Similarly to the price index, the unit index $Q_{i,c,z,t}$ of firm i in product category c , area z , and quarter t is:

$$Q_{i,c,z,t} = \sum_{u \in U_{i,c,z,t-1}} w_{u,z,t-1} \times (q_{u,z,t}/q_{u,z,t-1} - 1). \quad (4)$$

$P_{i,c,z,t}$ and $Q_{i,c,z,t}$ are winsorized at the 1% and 99% percentiles.

Third, we obtain the firm-pair-level cosine similarity of the geographic distribution of sales. We restrict to pairs of firms that sell in the same product module and have quarterly sales above \$100,000. We represent a firm i 's share of sales in each 3-digit zip code area in quarter t as a vector $v_{i,t}$ and calculate the cosine similarity for each firm-pair i and j :

$$s_{i,j,t} = \frac{v_{i,t} \cdot v_{j,t}}{\|v_{i,t}\| \|v_{j,t}\|}. \quad (5)$$

We keep all observations of untreated firms and the observations of all treated firms in a $[-6, 8]$ time window around the treatment, where quarter 0 is the quarter in which new board connections are formed. The $Treated \times Post$ variable equals one for treated units in the quarters post treatment and zero otherwise.

4.1.2 Product prices and quantities

To sharpen the definition of our treatment, we define new connections at the firm times product category times 3-digit zip code area level. That is, for each newly-connected firm-pair, we zoom into each 3-digit zip code area that both firms operate in and calculate the sum of their market shares within this area in the quarter right before the treatment. If their joint market share exceeds a threshold, we say that these two firms *in this area* are treated. By applying the threshold, we identify the actual product market overlap and rule out situations when two firms both operate in the same product category and the same geographic area but between themselves have inconsequential market share in that area.

Equipped with this sample, we estimate the following difference-in-differences regression,

$$Y_{i,c,z,t} = \alpha_1 \times DirectTreated_{i,c,z} \times Post_{i,c,z,t} + \alpha_2 \times IndirectTreated_{i,c,z} \times Post_{i,c,z,t} + \theta_{i,c,z} + \theta_{c,t} + \theta_{i,t} + \theta_{z,t} + e_{i,c,z,t}. \quad (6)$$

We include firm times product category times area fixed effects $\theta_{i,c,z}$ so that we are capturing the differential trends in outcome variables between the treated units and the control units rather than their baseline differences. We also include product category times quarter fixed effects $\theta_{c,t}$ and firm times quarter fixed effects $\theta_{i,t}$ to partial out within-product-category and within-firm time trends. As the same firm can produce in many product categories, and the peer firm it forms a board connection to might produce in some but not all same product categories, we can exploit variations within the same firm. In addition, we include area times quarter fixed effects $\theta_{z,t}$ to control for local economic dynamics that could correlate with the level of concentration in the local product markets. We cluster the standard errors at the firm level.

We report results using “product module” as the product category in Table 7. In column (1), we report the findings using the price index as the outcome variable with a threshold of at least 10% on the joint market share of the treated firm and its newly connected peer in the local market. We find that in the quarters post direct board connections, the per-quarter increase in product price is 0.22 p.p. faster for treated firms in their product modules that are affected by direct board connections compared to the rest, which corresponds to a 0.88 p.p. annualized difference. For indirect connections, the effects are 0.07 p.p., which is consistent with direct connections having a more prominent role at facilitating product market coordination than indirect connections. Both effects are statistically significant. In columns (2) and (3), we apply the thresholds of 5% and 3% on the market share in the local area. The magnitude of estimated treatment effects slightly decreases, which is consistent with a larger market share making coordination easier.

In columns (4)-(6), we use the unit index as the outcome variable. We find that the growth rates of units sold are significantly lower for the firms in their product categories that are treated with board connections. Such quantity suppression is consistent with the higher prices and collusive behavior.

We also repeat the aforementioned tests using the broader product category “product group” in the definition of treatments and product market outcomes and report the findings in Internet Appendix Table A5. While the broader classification leads to larger numbers of firms in each product category and more instances of connected firm-pairs, the products are

less similar and the definition of treatment is less precise. Consistent with this, we find that the magnitude of estimated treatment effects are smaller for both outcome variables.

In addition, we investigate the effects of board connections for non-focal-firm initiated changes and report them in Internet Appendix Table A6. We find that, similar to our main test, approximately half of the new indirect connections fall into this criteria. The estimates reported in Table 7 remain robust, suggesting that more exogenous board connections also have effects on product market outcomes.

4.1.3 Cosine similarity of sales portfolios

Bearing in mind that tacit market division is another anti-competitive tactic that firms could utilize to profit (Sullivan, 2020; De Leverano, 2023), we formally test how connected firms adjust their sales portfolios. We estimate the following model on this sample:

$$s_{i,j,t} = \alpha_1 \times DirectTreated_{i,j} \times Post_{i,j,t} + \alpha_2 \times IndirectTreated_{i,j} \times Post_{i,j,t} + \theta_t + \theta_{i,j} + e_{i,j,t} \quad (7)$$

where i and j are indices for the firms i and j , and t indexes the quarter. We include firm-pair fixed effects and quarter fixed effects, and cluster standard errors at the firm-pair level.

We report the results in Table 8. Column (1) shows that the cosine similarity score falls by 0.0037 on average after firm-pairs form indirect board connections, which is 3.69% of the within-firm-pair standard deviation (0.1004). However, we do not observe a drop in similarity following direct interlocks. Columns (2) and (3) further indicate that the results are robust to measuring similarity by county or by DMA (designated marketing area) of firm-pairs' sales. These suggest that firms adjust their geographic distribution and tilt away from one another post the formation of board connections, which is consistent with board connections enabling deliberate market division to avoid head-to-head competition.

These results also enlighten us about the differential mechanisms underlying direct and indirect board connections. While direct connections have much stronger effects on product market prices than indirect connections, only indirect connections are related to the tendency to avoid direct competition, which is a relatively more indirect anti-competitive practice.

4.2 Cross-sectional heterogeneities

We next perform six cross-sectional tests for our baseline analysis to further distinguish the anti-competitive effects from the internal efficiency improvements. We focus on such heterogeneous responses where two effects would be different, or when the anti-competitive effects are likely to be stronger. Specifically, we examine how the effects of board connections on profitability vary with: (1) exposure to Corporate Opportunity Waiver (COW); (2) whether the newly connected peers share common corporate customers; (3) the similarity in business descriptions of newly connected peers; (4) the geographical distance of newly connected peers; (5) the Herfindahl–Hirschman Index (HHI) of the treated firm’s industry; (6) the returns to scale of the treated firm’s industry.

To test our predictions, we estimate the following triple-differences model:

$$\begin{aligned}
 Y_{i,j,c,t} &= \alpha_1 \times Post_{c,t} + \alpha_2 \times Treated_{i,c} + \alpha_3 \times EventCharacteristic_c & (8) \\
 &+ \alpha_4 \times Post_{c,t} \times EventCharacteristic_c + \alpha_5 \times Treated_{i,c} \times EventCharacteristic_c \\
 &+ \beta_1 \times Treated_{i,c} \times Post_{c,t} + \beta_2 \times EventCharacteristic_c \times Treated_{i,c} \times Post_{c,t} \\
 &+ \theta_i + \theta_{j,t} + e_{i,j,c,t},
 \end{aligned}$$

where $EventCharacteristic_c$ is a sorting variable in the cross-section. It equals one for the time series of both the treated firm and its control firm if the new connections share common corporate customers or are in the top or bottom half in terms of a certain other characteristic.

4.2.1 By exposure to Corporate Opportunity Waivers (COWs)

Before the staggered introduction of COWs in some states, directors were subject to corporate opportunity doctrine, which prohibits directors from pursuing outside corporate opportunities without first presenting them to the company on the board of which they serve. The introduction of COWs reduced the legal risk of sharing information outside the board. Geng et al. (2023) suggest that COW introduction led to an increase in the frequency of board overlaps. Following Eldar and Grennan (2023), we consider a firm to be subject to COWs in or after the year when the law was introduced in the firm’s state of incorporation.

Internet Appendix Table A7 shows that board connections to product market peers are more frequent when the COWs are in effect. We find that firms are 2.3 p.p. more likely to form new board connections to product market peers when COWs are in effect, which is a 25% increase relative to the unconditional mean of 9.1 p.p.

We further study whether previously estimated profitability effects of board connections are larger when COWs are in place. Indeed, Panel A of Table 9 shows that while unconditional board connections significantly increase profitability, such increases are larger when COWs become effected. This evidence suggests that legal changes in recent decades might have exacerbated both the formation and anti-competitive effects of board connections.

4.2.2 By whether the newly connected peers share corporate customers

We expect the coordination benefits to be stronger when two firms share major corporate customers. To identify customer-supplier relationships in the network, we rely on firms' self-reported major customers from the WRDS Supply Chain dataset.²⁰ We find that out of all events, 383 of them are between peer firms that share a major customer.

Panel B of Table 9 reports estimates from our triple-difference regressions. For brevity, we pool events of new direct and indirect connections together and we only report the coefficients on the double-difference terms and the triple-difference terms. In the case of operating margin, we find that the effects are stronger when firms share major customers. While it rises by 0.8 p.p. when newly connected firms do not share major customers, the change becomes 2.6 p.p. when they do.

4.2.3 By similarity in the business descriptions between connected firms

We next sort the new board appointments based on the cosine similarity scores of business descriptions between the connected firms. We define a dummy variable, *TopSimilarity*, which equals one for the treated and control firms involved in events in which the new connections have a cosine similarity score above the sample median and additionally are in the same SIC-3 industry. We then implement the triple-differences regression model (8).

²⁰Please see Cen et al. (2016), Cen et al. (2017), and Cohen and Frazzini (2008) for the details on the construction of corporate customer-supplier data.

Panel C of Table 9 reports estimates from our triple-difference regressions. Consistent with Section 3, the coefficients on the double-difference terms are positive for all three outcome variables and statistically significant for operating margin and ROA. The triple-difference terms are also positive and are statistically significant for operating margin and ROA. New board connections lead to a 0.3 p.p. (0.6 p.p.; 0.5 p.p.) increase in gross margin (operating margin; ROA) for the subset of events where *TopSimilarity* is equal to zero, and these effects become 1.0 p.p. (2.0 p.p.; 1.3 p.p.) when *TopSimilarity* is equal to one. This provides evidence that the effects of new board connections are stronger between peers with more similar business descriptions and presumably operating closer in their product spaces.

4.2.4 By geographical distance between connected firms

A firm is more likely to share the product market with its peers that are geographically closer. Such peers are also more likely to be competitors with the treated firm in the raw material and labor markets. We examine whether the effects are stronger when the new connections are geographically closer. We sort events in each year based on the geographical distance between the headquarters' zip codes of the treated firm and its newly connected peer. Then we define an indicator variable, *CloseDistance*, which equals one for the time series of both the treated firm and its control if the events are in the bottom half in terms of the geographical distance between the treated firm and its new connections, and zero otherwise. Using this sorting variable, we estimate the triple-difference regression model (8).

Panel D of Table 9 reports estimates from these triple-difference regressions. The sign and magnitude of the double-difference terms are consistent with the results in Section 3. Moreover, the triple-difference terms are positive and statistically significant for operating margin and ROA. The effects are about twice larger when the new board connections are between firms that are located closer to each other. Overall, we find supportive evidence that the effects of new board connections are stronger between geographically closer peers.

4.2.5 By HHI of the treated firm's industry

Firms in more concentrated industries could find it easier to coordinate product market actions (Motta, 2004; Huck et al., 2004). To test if our results are stronger in concentrated

industries, we sort firms based on the HHI provided in Hoberg and Phillips (2016) and define *TopHHI* to equal one if the firm is in the top half in terms of its industry’s HHI.

Panel E of Table 9 reports estimates from triple-difference regressions (8). We see that the effects are indeed stronger in more concentrated industries, but the differential effects are not statistically significant. One potential reason for the lack of significance could be that firms in more concentrated industries might have alternative effective mechanisms to coordinate their behavior. We also recognize that the measures of HHI estimated based on publicly listed firm data might not reflect the actual degree of concentration in the industries (Ali et al., 2008). Possibly, this could also mean that the overall degree of industry concentration is not a necessary condition to take advantage of product market peer board connections.

4.2.6 By returns to scale of the treated firm’s industry

As an alternative to the HHI data based on publicly listed firms, we use the returns to scale in an industry as a proxy for the extent of competition. An industry is more likely to be oligopolistic if it exhibits increasing returns to scale. Following Dong et al. (2019), we estimate a two-factor Cobb-Douglas production function for each two-digit industry using data of the year 1999.²¹ We classify the firms according to whether their SIC-2 industry is experiencing above median returns to scale and estimate triple-difference regressions.

As reported in Panel F of Table 9, the effects of new board connections are stronger in industries that exhibit greater returns to scale – forming new board connections is followed by an increase in gross margin (operating margin; ROA) of 0.8 p.p. (1.6 p.p.; 1.1 p.p.) in industries with top half *ReturnstoScale*, while the rise is 0.4 p.p. (0.5 p.p.; 0.4 p.p.) in industries with bottom half *ReturnstoScale*.

4.3 Spillover effects

To further distinguish between the anti-competitive and efficiency-enhancing mechanisms, we also investigate the effects of new board connections on the common closest rivals of the newly connected firms. Suppose board connections enable anti-competitive practices such

²¹Please see Internet Appendix Table A1 for a more detailed description of this measure.

as price-fixing or suppressing labor or raw material prices. In such cases, we could expect that the closest rivals of the newly connected firms are also able to benefit from coordinating rivals. For example, being “under the umbrella of the cartel” (Bos and Harrington, 2010), they could raise the prices of the products to the same level as that of the product sold by newly connected firms. Even if they are not aware that their rivals became connected, they could follow the upward pricing trend in the market caused by the connected firms and benefit as free-riders (Deneckere and Davidson, 1985). However, if board connections enhance the internal efficiency of newly connected firms, their closest rivals could be put at a disadvantage, which can translate into worse firm profitability when faced with more efficient rivals. Hence, the direction of these spillover effects can help us establish the mechanism that drives an increase in the profitability of treated firms.

We identify firms subject to the spillovers (spillover firms) based on the events we identified in Section 2.2. Specifically, we define spillover firms to be firms that are among the ten closest Hoberg-Phillips peers of both sides of the new board connections and are not treated with new board connections themselves in the event year. Next, we repeat the matching procedure as in Section 2.2 with the only difference that we additionally require that the control firms are not subject to the spillovers in the event year. Our sample includes 686 unique spillover firm-years from new direct board connections, and 2,478 unique spillover firm-years from new indirect board connections.

Based on this matched sample, we estimate the following regression:

$$\begin{aligned}
 Y_{i,j,c,t} &= \alpha_1 \times Post_{c,t} + \alpha_2 \times DirectSpillover_{i,c} + \alpha_3 \times IndirectSpillover_{i,c} & (9) \\
 &+ \beta_1 \times DirectSpillover_{i,c} \times Post_{c,t} + \beta_2 \times IndirectSpillover_{i,c} \times Post_{c,t} \\
 &+ \theta_i + \theta_{j,t} + e_{i,j,c,t}.
 \end{aligned}$$

We report the results in Table 10. We find some evidence supportive of positive spillover effects. While the average gross margin of spillover firms from direct board connections does not evolve differently relative to control after the event, their operating margin and ROA significantly increase with magnitudes of 1.0 p.p. and 0.6 p.p. When we look at the spillover firms from indirect board connections, the estimated effects of the spillovers are positive but not statistically significant with magnitudes around 0.2 p.p. to 0.3 p.p.

In Internet Appendix Figure A2, we plot the coefficient estimates from a dynamic specification. Spillover firms do not trend differently relative to the control firms prior to the event, and consistent with Table 10 we see statistically significant and positive coefficients on the operating margin and ROA after the events when we focus on the firms subject to the spillovers from the direct board connections. Overall, these evidence corroborates the anti-competitive explanation of our main findings.

4.4 Connected director deaths

We next study instances of the deaths of directors who cross-sit on the boards of product market peers. The death of a director breaks the relationship between the two firms. We find 51 such instances and construct a treatment-control matched sample as before. The results are reported in Internet Appendix Table A8. We find that the affected firm’s gross margin (operating margin; ROA) drops by 1.8% (3.1%; 1.7%) following the death of the connected director, and the double-difference terms are statistically significant for operating margin and ROA. Despite the small sample size, this finding is consistent with the interpretation that the death of the linking director is followed by the discontinuation of coordination.

4.5 Convicted collusion cases

Do these new board connections also relate to the actual detected collusion cases? We obtain data on convicted collusion cases from the Private International Cartels Database (Connor, 2020). We acknowledge the caveats of studying detected cartels, as only about 10% to 30% of all cartel conspiracies are discovered (Connor, 2014), and those detected ones may not be the most economically important ones. Hence, this analysis is only suggestive.

We restrict the sample to firms headquartered in the US and hand-match those firms to the universe of firms we described in Section 2.2. We then construct a firm-pair-year level indicator of whether two firms are in an active detected cartel in a certain year. We also construct the degree of separation of each firm-pair in the network described in Section 2, which is the minimum number of intermediate nodes (i.e., firms) between two nodes that can connect them together. We exclude firm-pairs that are unconnected in the director network

or connected but with a degree of separation above four.

In Internet Appendix Figure A3, we plot the probability of a firm-pair having an active cartel in a certain year, conditional on the degree of separation of these two firms in the director network. We find that while two directly connected firms (zero degree of separation) have a probability of 0.058% of having an active detected cartel and it is 0.061% for a firm-pairs with one degree of separation, this probability becomes 0.017% for a firm-pairs with two degrees of separation and 0.004% for a firm-pairs with three degrees of separation. This strong associative relationship suggests the possibility of the director network’s role in facilitating anti-competitive practices.

We defer a detailed analysis of the detected cartel cases to Internet Appendix IA.3.

5 Robustness Tests

In this section, we share a number of robustness tests for our main results in Section 3. We first conduct a placebo test using non-product market peers. We also show that our main results are robust to alternative choices in the matching procedure, the specification of fixed effects, and industry classification. Lastly, we confirm the robustness of our main results to controlling for common ownership as well as customer-supplier relationships, strategic alliance, or joint ventures.

5.1 A placebo test using non-product market peers

We conduct a placebo test where instead of product market peers we study the effects of newly formed connections to non-product market peers on firm performance. We construct the sample as follows. For every firm-year in the Compustat-BoardEx merged dataset, we start by generating a random group of firms that we designate as the “pseudo industry” corresponding to that firm-year. We use this pseudo industry in place of the Hoberg-Phillips industry to identify direct and indirect board connections. We ensure that none of the firms in the pseudo industry are actually in the same Hoberg-Phillips industry and keep the size of the pseudo industry to be the same as the Hoberg-Phillips industry. We exclude the pseudo events that coincide with a new connection to an actual product market peer. Effectively,

we thus study how firm connections to non-product market peers affect performance after we keep the sizes of the pool of firms similar between actual product market peers (Hoberg-Phillips industry) and non-product market peers (pseudo industry).

For each pseudo treated firm, we find a control firm using the same matching procedure as in our main analysis. Then we estimate the regression (1) and report the results in Table 11. We do not find a statistically significant increase in profitability following the establishment of a board connection to a non-product market peer firm. That is, not all new board connections matter: the effects we document earlier do not come mechanically from any board connections but arise due to board connections to product market peers.

5.2 Robustness to director characteristics

We look at two director characteristics: whether they act as executives in one of the firms, and whether they are inbound or outbound appointments.

First, based on the Non-Executive Director indicator in BoardEx, we classify the new direct connections to involve executives if the director linking the newly connected firms is either an executive in the treated firm or an executive in its newly connected peer. Similarly, in the case of new indirect connections between product market peers A and C via an intermediary firm B, we classify the events to involve executives if Director X who connects firms A and B is an executive in A, or Director Y who connects firms B and C is an executive in C. Of the 1,493 events of new direct connections, 1,098 involve only non-executive directors while 395 involve at least one executive. Of the 4,085 events of new indirect connections, 2,886 only involve non-executive directors and 1,199 also involve an executive.

Next, we pool the four kinds of events identified above together and estimate double-differences regressions. The estimates reported in Internet Appendix Table A9 show positive and mostly statistically significant effects when looking at events that only involve non-executive directors, suggesting that the anti-competitive effects are also present in the connections via ordinary, non-executive board members. Still, the effects of board connections that involve executives are stronger than those that only involve non-executive directors. This is consistent with competition-sensitive information being more likely to flow across firms when directors involved in the board connections are also executives as such directors

are likely more engaged in firms' product market decisions than an average director.

Furthermore, in Internet Appendix Table A10, we compare new appointments to the board of the treated firm, i.e., inbound directors, to the cases when existing directors in the treated firm are appointed to a peer firm, i.e., outbound directors. We find no consistent pattern in the differences between the effects. These findings are more consistent with the anti-competitive mechanism than with internal efficiency improvements. The latter is more likely to be effectuated by newly appointed inbound directors.

5.3 Board connections or common ownership?

An active ongoing debate studies the role of common ownership in firm's anti-competitive behavior (Azar et al., 2018, 2022; Nain and Wang, 2018; Koch et al., 2021). For instance, Azar et al. (2018) found a positive correlation between common ownership concentration and flight ticket prices and discussed various potential mechanisms how common ownership can affect firm behavior. Indeed, one such mechanism can be shared board connections. An increase in common ownership between the treated firm and its product market peers can be accompanied by the establishment of new board connections. For example, an investor may appoint the same directors to its portfolio firms in the same industry. Even when a common investor appoints different directors to different firms, these directors might still belong to the same network and be more likely than a random director to simultaneously serve on a third intermediate firm. Indeed, Azar (2022) has shown a substantial overlap between firm common ownership and board interlock networks.

Noting these findings, we further study the possibility that the profitability-enhancing effects of board connections we discover purely stem from common ownership. We conduct the following robustness test. We use the firm-pair level measures of common ownership developed in Gilje et al. (2020) (GGL_{linear} , GGL_{fitted} , and $GGL_{full.attn}$).²² We first examine whether new board connections are associated with an increase in common ownership. We find that, around the treatment year, treated firms experience a larger increase in common ownership with its product market peers than control firms. The post-minus-prior increase in the mean GGL_{linear} (GGL_{fitted} ; $GGL_{full.attn}$) between treated firms and their product market

²²Please see Internet Appendix Table A1 for detailed descriptions of these measures.

peers is 1.42 (35.85; 1554.59) on average. For control firms, it is 1.12 (33.85; 1558.01). A two-sample T-test yields a statistic of 2.20 (1.42; 0.09). Hence, there seems to be an associative relationship between new board connections and concurrent *increases* in within-industry common ownership. Though untabulated, consistent with Azar (2022), the establishment of new board connections is also associated with a higher *level* of common ownership.

We next estimate the double-differences regressions (1) by pooling events of new direct and indirect connections together and additionally controlling for concurrent *changes* in within-industry common ownership,

$$\begin{aligned}
 Y_{i,j,c,t} &= \alpha_1 \times Post_{c,t} + \alpha_2 \times Treated_{i,c} + \beta_1 \times Treated_{i,c} \times Post_{c,t} & (10) \\
 &+ \gamma_1 \times \Delta(CommonOwnership)_{i,c} \times Post_{c,t} + \theta_i + \theta_{j,t} + e_{i,j,c,t}.
 \end{aligned}$$

$\Delta(CommonOwnership)_{i,c}$ is the change in the mean common ownership between a firm and all of its Hoberg-Phillips product market peers from $\tau = -3, -2, -1$ to $\tau = 0, 1, 2, 3$. We scale it by its sample standard deviation. It is a constant for each time series of seven years (from $\tau = -3$ to $+3$).

We report the findings in Table 12. Controlling for the dynamic effects of concurrent changes in within-industry common ownership, treated firms experience significantly higher growth in profitability compared to control firms. The coefficient estimates are similar to our main estimates in Table 5. This suggests that the profitability-enhancing effects of board connections are not fully capturing effects of potential concurrent increases in within-industry common ownership and present a related but distinct anti-competitive practice.

These regressions also reveal a strong positive associative relationship between changes in within-industry common ownership and the changes in profit margin. A one standard deviation increase in the post-minus-prior change in within-industry common ownership, when measured using GGL_{linear} , is associated with a 0.3 p.p. increase in the change of gross margin. While these coefficients do not necessarily bear a causal interpretation, their signs are consistent with anti-competitive effects of common ownership.²³

²³In untabulated tests, we find that the estimated effects of board connections are positive after controlling for an alternative common ownership measure κ (Amel-Zadeh et al., 2022) and are statistically significant when we use ROA as the outcome variable. Moreover, changes in the average κ between a firm and its

5.4 Robustness to alternative matching schemes

Internet Appendix Table A11 provides more robustness tests on the matching schemes.

5.4.1 Use two or three matches instead of one

Our baseline tests consider one control firm for each treated firm. The choice of how many control firms to include involves a trade-off between the efficiency and bias of our estimators. By using more control firms, we obtain more precise estimates at the cost of potentially greater bias due to the treated and control firms being less similar.

We now repeat the matching process with two or three control firms for each treated firm. As before, we require an exact match on Fama-French 17 industry and quantiles of the matching co-variates. While the matching co-variates are no longer as balanced statistically in the year prior to the event as in our baseline tests, the estimated effects of new board connections presented in Panels A and B are virtually identical to those in Table 5.

5.4.2 Match on the number of new appointments during the event year

We next address the concern that the appointment of new directors to the board by itself might have positive effects on profitability. For instance, new directors might put extra effort at the beginning of their tenure, possibly due to career concerns. The placebo tests, reported in Section 5.1 partially address this concern. Also, it is unlikely that this would confound the estimates from tests that focus on a more exogenous set of indirect connections where the focal firm does not experience a change in directors. Still, it could partially explain our baseline findings. Indeed, treated firms appoint on average one new director during the event year, while control firms appoint an average of 0.64 directors.

To address this concern, we refine the matching procedure and incrementally require that the treated firm and its control have exactly the same number of newly appointed directors during the event year. For 706 events of new direct connections and 2,224 events of new indirect connections, an exact match can be found and this constitutes our sample in Panel

product market peers are also positively correlated with changes in its profit margin. The sample size might be limited though as κ is only available for single-class S&P500 firms and we are only able to construct within-industry average κ for 13.7% of all observations.

C. Our estimates are similar to the main ones.

5.4.3 Match additionally on other co-variates

Table 2 shows that treated and control firms are not statistically significantly different in terms of co-variates used in matching. Also, we do not see pre-trends in Figure 2, so any residual unbalancedness in firm characteristics is unlikely to be driving our main findings. However, we now provide robustness tests where we modify the matching procedure.

In Panel D of Table A11, we use operating margin instead of gross margin. Also, we include extra co-variates in addition to assets, gross margin, and Tobin's Q. We sequentially add operating margin, sales growth, ROA, R&D to assets, and CAPEX to assets, and report results in Panels E, F, G, H, and I, respectively. We also match on all variables in Panel J. Our main findings are similar to those under the new matching schemes.

5.4.4 Require that the control firm is never treated before or during [-3, 3]

In the matching process, we require that the control firm is not treated in the event year. Nonetheless, it is possible that it might be treated a few years before the event or right after. To avoid such treatments affecting our estimates, we additionally require that the control firm is never treated during the [-3, 3] window around the event year in Panel K. In Panel L, we additionally require that the control firm is never treated both during or before the [-3, 3] window. Our main findings are unaffected by these alternative choices.²⁴

5.5 Robustness to alternative specifications of fixed effects

In all regressions we estimate, we include industry times year fixed effects and firm-specific fixed effects. With the industry times year fixed effects we can further rule out the possibility that some industry-level trends coincide with our events of new connections. In Internet Appendix Table A12 we provide robustness to the fixed effect structures. Panels A and B show that the estimates are robust to using alternative industry definitions such as SIC-3

²⁴As we use stacked regression estimators and already-treated firms never act as effective control units in Panel L, our estimates stand to the critique in Baker et al. (2022) on difference-in-differences estimates.

and FIC-200 to define industry times year fixed effects. This gives us confidence that our estimates are not capturing industry-level common trends.

Second, in all specifications we include firm fixed effects and so we are comparing differences in the post-to-prior changes between treated and control firms. Panel C reports the estimates when we instead control for firm-cohort fixed effects, where a cohort corresponds to observations of a treated firm and its matched control. Thus we have a fixed effect for each time a firm appears as a treated or a control firm in our sample. These fixed effects are more granular than firm fixed effects and our findings are robust to including them.

5.6 Robustness to alternative clustering

In our baseline tests, we cluster the standard errors at the firm level. It is possible that the outcome variables of connected firm-pairs are highly positively correlated and treating them as independent units can lead us to inflating the power of the tests. We define a new unit of clustering, which is all observations of a connected firm-pair for treated firms and all observations of a single firm for control firms. As shown in Internet Appendix Table A13, while the T-stats drop slightly for some estimates, they all remain statistically significant.

5.7 Robustness to alternative industry classification

In Internet Appendix Table A14, we further provide robustness to the definitions of industry peers. Instead of defining them according to the product-market based Hoberg-Phillips classification, Panel A uses the competitors disclosed by firms and recorded in FactSet Supply Chain Relationships (formerly, Revere) database. Panel B instead defines industry peers based on the SIC-3 industry, while Panel C uses the SIC-4 industry. Further, Panels D and E use the GICS 6-digit industry and the GICS 8-digit industry. We find confirming evidence of an increase in profitability after new industry peer board connections get formed.

5.8 Robustness to other connections between firms

One might argue that the Hoberg-Phillips industry classification can capture customer-supplier relationships instead of product market rivalry, as a customer firm and its supplier

can also have similar languages in their business descriptions. Such connections may have positive effects on a firm’s profitability for reasons outside of the scope of anti-competitive practices. To address this concern, we check if any of the new board connections we identify are between customer and supplier firms.

We find that out of all events used in Table 5, only 68 of them are between pairs of customer-supplier firms based on the WRDS Supply Chain dataset. We then estimate the double-differences regressions (1) by additionally controlling for such events. As reported in Internet Appendix Table A15, our main findings are very similar if we focus on board connections between firms that are not customer-supplier pairs. We find some weak evidence that board connections have stronger effects on profitability when the two firms are not only Hoberg-Phillips peers but also a pair of customer-supplier firms.

We also investigate the possibility that the increased profitability comes from strategic alliance or joint ventures. Using the Securities Data Company (SDC) Database, we find that 213 events are between firms that ever formed strategic alliance or started joint ventures during our sample period. In Internet Appendix Table A16, we show that baseline estimates are robust to controlling for such events. This makes us more confident that we are not capturing effects of explicit agreements among firms which antitrust authorities usually deem as benign and not anti-competitive in nature.

6 Conclusion

Taking advantage of the networks formed by interlocking directorships and the text-based Hoberg-Phillips industry classification, we find that board connections to product market peers have positive profitability implications. Specifically, a firm’s gross margin rises by an average of 0.8 p.p. after forming new direct connections to product market peers and by 0.4 p.p. after forming new indirect connections to product market peers via an intermediate firm. A back-of-the-envelope calculation suggests that direct and indirect connections can create as much value as \$6.21 million and \$3.11 million per year for a median firm. We address endogeneity concerns by exploring the network structure and focusing on new connections that are unlikely to be correlated with future firm prospects.

We remain agnostic over the specific strategy and form of anti-competitive practices that board connections facilitate between peer firms. Connected firms might engage in market segmentation and target separate product categories, demographic groups, or geographic areas, and wield market power in their respective market segments, or they might sell in the same market and fix the product prices at a high level. The coordination can come via pure information exchange, or alternatively the social network could bring trust among competing firms and make market segmentation or price-fixing more sustainable. Using scanner data in the consumer goods sector, we do however find that such connections are associated with higher product prices and a greater tendency to avoid head-on competition.

We also cannot speak of the full extent of board's role in anti-competitive practices or its economic consequences for firms, as we identify the effects of incremental board connections to product market peers rather than the stock of board connections.

With that said, this paper has several important regulatory implications. First, our findings indicate the role of directors in anti-competitive practices and provide support for the current ban on interlocking directorships between competing firms. Second, the results suggest that text-based analyses are powerful in identifying competitors in the marketplace and can have the potential to aid the execution of antitrust regulations. In addition, we find that indirect connections via an intermediate firm also have positive effects on profitability, albeit their economic magnitudes are smaller than those of direct connections. This argues for going beyond interlocking directorships and putting restraints on indirect board connections between competitors as well, especially in cases where the detrimental effects of anti-competitive practices on consumer welfare are substantial.

Total	1,493	100.0%	4,085	100.0%	5,578	100.0%

Note: This table reports the distribution of treated firms in the Fama-French 48-industry classification.

Table 2: Comparison of treated and matched control firms

	Treated			Control			Dif	T-stat	Compustat Sample	
	Mean	SD	N	Mean	SD	N			Mean	SD
<i>Variables used in matching</i>										
Assets	6.71	1.85	5,578	6.68	1.86	5,578	0.04	1.0	6.58	2.04
Gross Margin	0.51	0.26	5,578	0.51	0.24	5,578	0.00	0.9	0.42	0.24
Tobin's Q	2.67	2.03	5,578	2.62	1.88	5,578	0.06	1.6	1.82	1.40
<i>Variables not used in matching</i>										
Operating Margin	0.13	0.20	5,571	0.17	0.18	5,558	-0.04	-12.0	0.18	0.19
ROA	0.09	0.12	5,571	0.13	0.11	5,558	-0.03	-15.2	0.09	0.11
Sales Growth	0.22	0.50	5,253	0.17	0.38	5,291	0.05	5.5	0.14	0.38
SG&A to Sales	0.41	0.27	5,248	0.35	0.24	5,320	0.06	11.6	0.28	0.20
Depreciation & Amortization to Sales	0.07	0.10	5,571	0.07	0.10	5,558	0.00	1.0	0.06	0.08
R&D to Assets	0.11	0.11	4,507	0.07	0.08	3,918	0.03	15.4	0.06	0.08
CAPEX to Assets	0.05	0.06	5,561	0.05	0.06	5,553	-0.00	-1.2	0.04	0.06
Firm Age	24.45	17.55	5,578	26.76	18.30	5,578	-2.32	-6.8	26.76	20.40

Note: This table reports the summary statistics for the treated and control firms in the year prior to the treatment (i.e., the year for which firm characteristics are used in the matching procedure) and also for all firms in Compustat.

Table 3: Cumulative abnormal returns (CARs) around announcement dates

	Average CARs	
	(1) Abnormal returns from the market model	(2) Firm returns minus market returns as abnormal returns
Direct Connections	0.83%* (1.91)	0.91%** (2.23)
Observations	396	396
Indirect Connections	0.73%* (1.89)	0.62%* (1.71)
Observations	424	424
Other Appointments	0.23%*** (4.29)	0.22%*** (4.23)
Observations	25,459	26,821

Note: This table reports the average CARs during a seven-day window around the announcement dates of director appointments. We report CARs both for appointments that cause board connections between product market peers to form and for all other appointments. In column (1), we estimate a market model using stock returns between [-300, -60] calendar days before the announcement dates and the CRSP NYSE/NY-SEMKT/Nasdaq Value-Weighted Market Index. Then we calculate abnormal returns using our estimated model. In column (2), we calculate abnormal returns as firm returns minus market returns. We winsorize daily returns at the 1% and 99% percentiles before estimating the market model. We also winsorize CARs at the 1% and 99% percentiles. T-stats are in parentheses. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$.

Table 4: Proportion of newly connected peers that are in the same SIC/GICS industry

	Direct New Connections		Indirect New Connections	
	(1) Newly Connected Peers	(2) All H-P peers	(3) Newly Connected Peers	(4) All H-P Peers
<i>Using SIC Industry Classification</i>				
Same SIC-2 industry	62.0%	50.4%	65.3%	51.1%
Same SIC-3 industry	55.2%	44.7%	58.5%	45.2%
Same SIC-4 industry	34.4%	26.4%	40.3%	26.5%
<i>Using GICS Industry Classification</i>				
Same GGROUP Industry	75.2%	61.7%	76.1%	61.6%
Same GIND Industry	58.6%	45.8%	61.6%	45.2%
Same GSUBIND Industry	44.2%	34.2%	48.9%	33.5%

Note: Columns (1) and (3) report the proportion of newly connected Hoberg-Phillips peers that are in the same SIC/GICS industry as the treated firms. Columns (2) and (4) report the proportion of all Hoberg-Phillips peers of the treated firm that are in the same SIC/GICS industry as the treated firm, averaged across all the treated firms. A two-sample T-test between columns (1) and (2) or between columns (3) and (4) shows a difference significant at the 1% level.

Table 5: Double-difference regressions

Panel A: Main findings

	(1)	(2)	(3)	(4)
	Gross Margin	Operating Margin	ROA	Sales Growth
Post	-0.007*** (-4.27)	-0.008*** (-4.77)	-0.007*** (-6.12)	-0.020*** (-5.23)
DirectTreated \times Post	0.008** (2.45)	0.014*** (3.86)	0.009*** (3.52)	-0.023*** (-2.60)
IndirectTreated \times Post	0.004* (1.88)	0.008*** (3.59)	0.007*** (4.01)	-0.004 (-0.75)
Observations	68,690	68,534	68,602	67,033
Firm FE	Yes	Yes	Yes	Yes
FF48 \times Year FE	Yes	Yes	Yes	Yes
Clustering	Firm	Firm	Firm	Firm
# of Matched Controls	1	1	1	1
Within R-squared	0.001	0.001	0.002	0.002
P-value from a Test of DirectTreated \times Post = IndirectTreated \times Post	0.24	0.12	0.42	0.04

Panel B: Robustness of results to regression specification

	(1)	(2)	(3)
	Gross Margin	Gross Margin	Gross Margin
Post	-0.007*** (-4.08)	-0.004 (-1.26)	-0.008*** (-3.96)
DirectTreated \times Post	0.008** (2.29)	0.008* (1.94)	
IndirectTreated \times Post	0.004* (1.81)		0.004* (1.75)
Observations	68,682	17,965	50,607
Firm-Cohort FE	Yes		
Firm FE		Yes	Yes
FF48 \times Year FE	Yes	Yes	Yes
Clustering	Firm	Firm	Firm
# of Matched Controls	1	1	1
Within R-squared	0.001	0.000	0.001

Note: Panel A of this table reports results from the following regression using the sample of all events,

$$\begin{aligned}
 Y_{i,j,c,t} &= \alpha_1 \times Post_{c,t} + \alpha_2 \times DirectTreated_{i,c} + \alpha_3 \times IndirectTreated_{i,c} \\
 &+ \beta_1 \times DirectTreated_{i,c} \times Post_{c,t} + \beta_2 \times IndirectTreated_{i,c} \times Post_{c,t} + \theta_i + \theta_{j,t} + e_{i,j,c,t}.
 \end{aligned}$$

Here i is the index for each firm, j is the index for each industry, c is the index for each cohort which consists of all observations of a treated firm and its matched control, and t is the index for each calendar year. $Post_{c,t}$ is one for both treated and control firms for the years $\tau = 0, 1, 2,$ and 3 , where $\tau = 0$ is the treatment year, and is zero for the years $\tau = -3, -2,$ and -1 . Coefficient on $Post_{c,t}$ is the estimated difference between prior and post for the control firm. $DirectTreated_{i,c}$ is a dummy variable equal to one for the treated firms that experience a direct board connection to a product market peer while $IndirectTreated_{i,c}$ is a dummy variable equal to one for the treated firms that experience a new indirect board connection to a product market peer. $DirectTreated_{i,c} \times Post_{c,t}$ and $IndirectTreated_{i,c} \times Post_{c,t}$ are the double-difference terms, the coefficient estimates of which are the estimated effects of new board connections to product market peers. θ_i are firm fixed effects. $\theta_{j,t}$ are industry times year fixed effects based on the Fama-French 48-industry classification. We omit coefficients of $DirectTreated_{i,c}$ and $IndirectTreated_{i,c}$ from the table. We also report the p-value from a test for the equality of the effects of a direct connection and the effects of an indirect connection. Panel B shows that our main results are robust to using firm-cohort fixed effects as in Gormley and Matsa (2011) or separating events of direct and indirect connections. Internet Appendix Table A12 shows that results in this table are robust to other alternative specification of fixed effects. T-stats are in parentheses. Standard errors are clustered at the firm level. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$.

Table 6: Double-difference regressions, using the non-focal-firm initiated subset of events

	(1)	(2)	(3)	(4)
	Gross Margin	Operating Margin	ROA	Sales Growth
Post	-0.009*** (-3.34)	-0.011*** (-4.23)	-0.010*** (-5.17)	-0.023*** (-3.79)
ExogenousTreated \times Post	0.007** (2.25)	0.011*** (2.99)	0.009*** (3.63)	-0.008 (-0.95)
Observations	26,065	26,016	26,032	25,473
Firm FE	Yes	Yes	Yes	Yes
FF48 \times Year FE	Yes	Yes	Yes	Yes
Clustering	Firm	Firm	Firm	Firm
# of Matched Controls	1	1	1	1
Within R-squared	0.001	0.002	0.002	0.002

Note: This table reports results from the following regression using the subset of events that are non-focal-firm initiated,

$$\begin{aligned}
 Y_{i,j,c,t} = & \alpha_1 \times Post_{c,t} + \alpha_2 \times ExogenousTreated_{i,c} + \\
 & + \beta_1 \times ExogenousTreated_{i,c} \times Post_{c,t} + \theta_i + \theta_{j,t} + e_{i,j,c,t}.
 \end{aligned}$$

Here $Post_{c,t}$ is one for both treated and control firms for the years $\tau = 0, 1, 2,$ and $3,$ where $\tau = 0$ is the treatment year. Coefficient on $Post_{c,t}$ is the estimated difference between prior and post for the control firm. $ExogenousTreated_{i,c} \times Post_{c,t}$ is the double difference term, the coefficient of which is the estimated effects of non-focal-firm initiated new board connection with peer firms. θ_i are firm fixed effects. $\theta_{j,t}$ are industry times year fixed effects based on the Fama-French 48-industry classification. T-stats are in parentheses. We omit the coefficient of $ExogenousTreated_{i,c}$ from the table. Standard errors are clustered at the firm level. *** $p < 0.01,$ ** $p < 0.05,$ * $p < 0.1.$

Table 7: Effects on product market price and quantity using barcode-level data

	(1) Price Index	(2) Price Index	(3) Price Index	(4) Unit Index	(5) Unit Index	(6) Unit Index

Clustering	Firm	Firm	Firm	Firm	Firm	Firm
Threshold on Market Share	10%	5%	3%	10%	5%	3%
Within R-squared	0.000	0.000	0.000	0.000	0.000	0.000

Note: This table reports results from the following regression,

$$Y_{i,c,z,t} = \alpha_1 \times DirectTreated_{i,c,z} \times Post_{i,c,z,t} + \alpha_2 \times IndirectTreated_{i,c,z} \times Post_{i,c,z,t} + \theta_{i,c,z} + \theta_{c,t} + \theta_{i,t} + \theta_{z,t} + e_{i,c,z,t},$$

where $y_{i,c,z,t}$ is the price index $p_{i,c,z,t}$ or unit index $q_{i,c,z,t}$ of firm i in product module c in 3-digit zip code area z in quarter t . $DirectTreated_{i,c,z} \times Post_{i,c,z,t}$ ($IndirectTreated_{i,c,z} \times Post_{i,c,z,t}$) equals zero for those firm-product-module-zip3 combinations that are never treated and for treated firm-product-module-zip3 in quarters prior to the treatment of direct (indirect) board connections and equals one for treated firm-product-module-zip3 in quarters post the treatment. $\theta_{i,c,z}$ are firm times product module times zip3 fixed effects. $\theta_{c,t}$ are product module times quarter fixed effects. $\theta_{i,t}$ are firm times quarter fixed effects. $\theta_{z,t}$ are area times quarter fixed effects. In columns (1)-(3) we use price index as the outcome variable and in columns (4)-(6) we use unit index instead. T-stats are in parentheses. Standard errors are clustered at the firm level. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$.

Table 8: Effects on cosine similarity of geographic distribution using barcode-level data

	(1) Similarity by Zip-3	(2) Similarity by County	(3) Similarity by DMA
DirectTreated \times Post	0.004831 (0.87)	0.003252 (0.64)	0.005302 (0.94)
IndirectTreated \times Post	-0.003716** (-2.35)	-0.005125*** (-3.91)	-0.004396*** (-2.66)
Observations	23,051,386	23,051,386	23,051,386
Firm-Pair FE	Yes	Yes	Yes
Quarter FE	Yes	Yes	Yes
Clustering	Firm-Pair	Firm-Pair	Firm-Pair
Within R-squared	0.000	0.000	0.000

Note: This table reports results from the following regression,

$$s_{i,j,t} = \alpha_1 \times \text{DirectTreated}_{i,j} \times \text{Post}_{i,j,t} + \alpha_2 \times \text{IndirectTreated}_{i,j} \times \text{Post}_{i,j,t} + \theta_t + \theta_{i,j} + e_{i,j,t}$$

where i and j are indexes for the pair firm i and firm j and t is the index for the quarter. $\text{DirectTreated}_{i,j} \times \text{Post}_{i,j,t}$ ($\text{IndirectTreated}_{i,j} \times \text{Post}_{i,j,t}$) equals zero for those firm-pairs that are never treated and for treated firm-pairs in quarters prior to the treatment of direct (indirect) board connections and equals one for treated firm-pairs in quarters post the treatment. We include firm-pair fixed effects $\theta_{i,j}$ and quarter fixed effects θ_t . T-stats are in parentheses. Standard errors are clustered at the firm level. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$.

Firm FE	Yes	Yes	Yes
FF48 \times Year FE	Yes	Yes	Yes
Clustering	Firm	Firm	Firm
# of Matched Controls	1	1	1

Note: Panel A of this table reports estimates from the following regression

$$\begin{aligned}
Y_{i,j,c,t} = & \alpha_1 \times Post_{c,t} + \alpha_2 \times Treated_{i,c} + \alpha_3 \times COWsInEffect_{i,t} \\
& + \alpha_4 \times Post_{c,t} \times COWsInEffect_{i,t} + \alpha_5 \times Treated_{i,c} \times COWsInEffect_{i,t} \\
& + \beta_1 \times Treated_{i,c} \times Post_{c,t} + \beta_2 \times Treated_{i,c} \times Post_{c,t} \times COWsInEffect_{i,t} \\
& + \theta_i + \theta_{j,t} + e_{i,j,c,t}.
\end{aligned}$$

Panels B-F report estimates from the following regression,

$$\begin{aligned}
Y_{i,j,c,t} = & \alpha_1 \times Post_{c,t} + \alpha_2 \times Treated_{i,c} + \alpha_3 \times EventCharacteristic_c \\
& + \alpha_4 \times Post_{c,t} \times EventCharacteristic_c + \alpha_5 \times Treated_{i,c} \times EventCharacteristic_c \\
& + \beta_1 \times Treated_{i,c} \times Post_{c,t} + \beta_2 \times EventCharacteristic_c \times Treated_{i,c} \times Post_{c,t} \\
& + \theta_i + \theta_{j,t} + e_{i,j,c,t}.
\end{aligned}$$

Here $Treated_{i,c}$ equals one for the time series of a firm experiencing new direct or indirect connections to product market peers, and zero otherwise. In this regression we pool events of new direct and indirect connections together. $Post_{c,t}$ is one for both treated and control firms for the years $\tau = 0, 1, 2,$ and $3,$ where $\tau = 0$ is the treatment year. $COWsInEffect_{i,t}$ equals one if COWs are in effect in year t in the state where firm i was incorporated. $EventCharacteristic_c$ is a sorting variable in the cross-section. It equals one for the time series of both the treated firm and its control if the new connections share common corporate customers or are in the top or bottom half in terms of a certain characteristic. $Treated_{i,c} \times Post_{c,t}$ is the double-difference term, the coefficient of which is the estimated effects of new connections in the subsample where $EventCharacteristic_c$ or $COWsInEffect_{i,t}$ takes the value of zero. $EventCharacteristic_c \times Treated_{i,c} \times Post_{c,t}$ ($COWsInEffect_{i,t} \times Treated_{i,c} \times Post_{c,t}$) is the triple-difference term, the coefficient of which is the estimated incremental effects of new connections where $EventCharacteristic_c$ ($COWsInEffect_{i,t}$) takes the value of one relative to where $EventCharacteristic_c$ ($COWsInEffect_{i,t}$) takes the value of zero. θ_i are firm fixed effects. $\theta_{j,t}$ are industry times year fixed effects based on the Fama-French 48-industry classification. For brevity, only coefficients of the double-difference and triple-difference terms are reported in the table. T-stats are in parentheses. Standard errors are clustered at the firm level. *** $p < 0.01,$ ** $p < 0.05,$ * $p < 0.1.$

Table 10: Spillover effects of board connections to closest rivals

	(1)	(2)	(3)

# of Matched Controls	1	1	1
Within R-squared	0.000	0.001	0.001

Note: This table reports results from the following regression using the sample of firms subject to spillover effects from new board connections,

$$\begin{aligned}
Y_{i,j,c,t} &= \alpha_1 \times Post_{c,t} + \alpha_2 \times DirectSpillover_{i,c} + \alpha_3 \times IndirectSpillover_{i,c} \\
&+ \beta_1 \times DirectSpillover_{i,c} \times Post_{c,t} + \beta_2 \times IndirectSpillover_{i,c} \times Post_{c,t} + \theta_i + \theta_{j,t} + e_{i,j,c,t}.
\end{aligned}$$

Here $Post_{c,t}$ is one for both treated and control firms for the years $\tau = 0, 1, 2,$ and $3,$ where $\tau = 0$ is the treatment year. Coefficient on $Post_{c,t}$ is the estimated difference between prior and post for the control firm. $DirectSpillover_{i,c}$ equals one for the time series of a firm affected by spillover from new direct connections. $IndirectSpillover_{i,c}$ equals one for the time series of a firm affected by spillover from new indirect connections. θ_i are firm fixed effects. $\theta_{j,t}$ are industry times year fixed effects based on the Fama-French 48-industry classification. We omit coefficients of $DirectSpillover_{i,c}$ and $IndirectSpillover_{i,c}$ from the table. T-stats are in parentheses. Standard errors are clustered at the firm level. *** $p < 0.01,$ ** $p < 0.05,$ * $p < 0.1.$

Table 11: A placebo test using non-product market peers

	(1)	(2)	(3)
	Gross Margin	Operating Margin	ROA

$\Delta(\text{Common Ownership}) \times \text{Post}$	0.005*** (4.68)	0.008*** (5.98)	0.004*** (3.58)
<i>Panel C: Using GGL_{full_attn}</i>			
Treated \times Post	0.004 (1.39)	0.009*** (3.22)	0.008*** (3.58)
$\Delta(\text{Common Ownership}) \times \text{Post}$	0.003*** (2.71)	0.002* (1.86)	0.000 (0.02)
Observations	40,408	40,302	40,343
Firm FE	Yes	Yes	Yes
FF48 \times Year FE	Yes	Yes	Yes
Clustering	Firm	Firm	Firm
# of Matched Controls	1	1	1

Note: This table reports results from the following regression,

$$\begin{aligned}
 Y_{i,j,c,t} &= \alpha_1 \times Post_{c,t} + \alpha_2 \times Treated_{c,t} + \beta_1 \times Treated_{i,c} \times Post_{c,t} \\
 &+ \gamma_1 \times \Delta(\text{CommonOwnership})_{i,c} \times Post_{c,t} + \theta_i + \theta_{j,t} + e_{i,j,c,t}.
 \end{aligned}$$

Here $Post_{c,t}$ is one for both treated and control firms for the years $\tau = 0, 1, 2,$ and $3,$ where $\tau = 0$ is the treatment year. $Treated_{i,c}$ equals one for the time series of a firm experiencing new direct or indirect connections to product market peers, and zero otherwise. In this regression we pool events of new direct and indirect connections together. $\Delta(\text{CommonOwnership})_{i,c}$ is the change in the mean common ownership between a firm and all its Hoberg-Phillips product market peers from $\tau = -3, -2, -1$ to $\tau = 0, 1, 2, 3.$ It is a constant for each time series of length 7 (from $\tau = -3$ to $+3$). We use firm-pair level measures of common ownership as constructed in Gilje et al. (2020), which are $GGL_{linear}, GGL_{fitted},$ and $GGL_{full_attn}.$ The sample size shrinks relative to Table 5 as the measures of common ownership are only available for the years 2000-2012. For brevity, only coefficients of $Treated_{i,c} \times Post_{c,t}$ and $\Delta(\text{CommonOwnership})_{i,c} \times Post_{c,t}$ are reported in the table. T-stats are in parentheses. Standard errors are clustered at the firm level. *** $p < 0.01,$ ** $p < 0.05,$ * $p < 0.1.$

Figure 1: Distribution of cosine similarity score

Panel A: Similarity between new direct connections

Note: The average score is 0.046 for new direct connections and 0.046 for all Hoberg-Phillips peers. The p-value is 0.91 in a two-sample T-test and 0.43 in a Kolmogorov-Smirnov test.

Panel B: Similarity between new indirect connections

Note: The average score is 0.042 for new indirect connections and 0.041 for all Hoberg-Phillips peers. The p-value is 0.03 in a two-sample T-test and 0.01 in a Kolmogorov-Smirnov test.

Note: This figure presents the empirical distribution of the cosine similarity score between the treated firms and their newly connected Hoberg-Phillips peers, along with the cosine similarity score between the treated firms and all their Hoberg-Phillips peers. The scores are winsorized at the 99% percentile.

Figure 2: Plots of the dynamics of the difference between treated and control firms

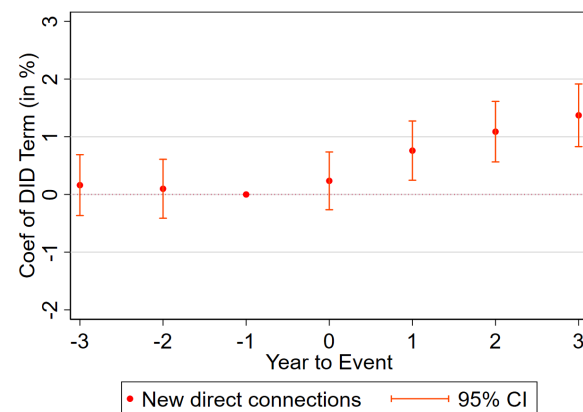

Panel A1: Gross margin, direct

Panel B1: Operating margin, direct

Panel C1: ROA, direct

Panel A2: Gross margin, indirect

Panel B2: Operating margin, indirect

Panel C2: ROA, indirect

Note: This figure plots coefficients from the following regression,

$$\begin{aligned}
Y_{i,j,c,t} &= \alpha_1 \times DirectTreated_{i,c} + \alpha_2 \times IndirectTreated_{i,c} \\
&+ \sum_{s=-3}^{-2} \beta_s \times \mathbb{1}(\tau = s)_{c,t} + \sum_{s=0}^3 \beta_s \times \mathbb{1}(\tau = s)_{c,t} \\
&+ DirectTreated_{i,c} \times \left(\sum_{s=-3}^{-2} \gamma_s \times \mathbb{1}(\tau = s)_{c,t} + \sum_{s=0}^3 \gamma_s \times \mathbb{1}(\tau = s)_{c,t} \right) \\
&+ IndirectTreated_{i,c} \times \left(\sum_{s=-3}^{-2} \delta_s \times \mathbb{1}(\tau = s)_{c,t} + \sum_{s=0}^3 \delta_s \times \mathbb{1}(\tau = s)_{c,t} \right) \\
&+ \theta_i + \theta_{j,t} + e_{i,j,c,t}.
\end{aligned}$$

Here t represents the calendar year and τ represents the year relative to the treatment. $\mathbb{1}(\tau = s)_{c,t}$ is a dummy variable that is equal to one if the observation is $-s$ years before the treatment (for $s = -3, -2$) or if the observation is s years after the treatment (for $s = 0, 1, 2, 3$). We omit the dummy variables for the year prior to the event, i.e., $\tau = -1$, which forms the baseline year. Thus all the effects we document are relative to this year. The estimates of γ_s and δ_s capture the difference in outcome variables between treated and control firms of year s relative to their difference in the baseline year. Standard errors are clustered at the firm level.

Figure 3: Illustration of non-focal-firm initiated board connection changes

Note: This figure illustrates an example of the non-focal-firm initiated board connection changes we discuss in Section 3.3. Firm 1 is the treated firm, i.e., the focal firm, and firm 2 is its product market peer. Firm 3 is the intermediate firm.

Figure 4: Plots of the dynamics of the difference between treated and control firms, using the non-focal-firm initiated subset of events

63

Note: This figure plots coefficients from the following regression,

$$\begin{aligned}
 Y_{i,j,c,t} = & \alpha_1 \times ExogenousTreated_{i,c} + \sum_{s=-3}^{-2} \beta_s \times \mathbb{1}(\tau = s)_{c,t} + \sum_{s=0}^3 \beta_s \times \mathbb{1}(\tau = s)_{c,t} \\
 & + ExogenousTreated_{i,c} \times \left(\sum_{s=-3}^{-2} \gamma_s \times \mathbb{1}(\tau = s)_{c,t} + \sum_{s=0}^3 \gamma_s \times \mathbb{1}(\tau = s)_{c,t} \right) + \theta_i + \theta_{j,t} + e_{i,j,c,t}.
 \end{aligned}$$

Here t represents the calendar year and τ represents the year relative to the treatment. $\mathbb{1}(\tau = s)_{c,t}$ is a dummy variable that is equal to one if the observation is $-s$ years before the treatment (for $s = -3, -2$) or if the observation is s years after the treatment (for $s = 0, 1, 2, 3$). We omit the dummy variables for the year prior to the event, i.e., $\tau = -1$, which forms the baseline year. Thus all the effects we document are relative to this year. The estimates of γ_s capture the difference in outcome variables between treated and control firms of year s relative to their differences in the baseline year. Standard errors are clustered at the firm level.

Internet Appendix

IA.1 Supplementary Tables and Figures

Table A1: List of variables in the main test

Panel A: Financial and accounting variables

Assets	The natural logarithm of the firm's total assets ($\log(at)$)
Gross Margin	The ratio of gross profit to sales ($gp/sale$)
Operating Margin	The ratio of operating income before depreciation and amortization to sales ($oibdp/sale$)
ROA	The ratio of operating income before depreciation and amortization to total assets ($oibdp/at$)
Sales Growth	The percentage change of sales relative to the prior year ($(sale-l.sale)/l.sale$)
Tobin's Q	The ratio of market value of equity plus book value of debt over total assets ($(at+csho \times prccf - ceq)/at$)

Panel B: Indicator variables used in regressions

DirectTreated	A dummy variable that equals one for the time series of a firm experiencing new direct connections to product market peers
IndirectTreated	A dummy variable that equals one for the time series of a firm experiencing new indirect connections to product market peers
Post	A dummy variable that equals zero for $\tau = -3, -2, -1$, and equals one for $\tau = 0, 1, 2$, and 3
ExogenousTreated	A dummy variable that equals one for the time series of a firm experiencing new indirect connections to product market peers that occur due to changes on the board of another firm rather than itself
PseudoDirectTreated	A dummy variable that equals one for the time series of a firm experiencing direct connections to pseudo peers
PseudoIndirectTreated	A dummy variable that equals one for the time series of a firm experiencing indirect connections to pseudo peers

Table A1: List of variables in the main test (continued)

Panel C: Sorting variables

If Share Major Customers	Whether the connected firm-pair has common major customer firms, i.e., those accounting for more than 10% of their total sales according to their annual disclosure
Similarity Score	The cosine similarity scores between the treated firm and its new connections (Hoberg and Phillips, 2010, 2016). If an event involves a new connection between a treated firm and multiple product market peers, it takes the value of the largest cosine similarity score
Top Similarity	A dummy that equals one for the time series of both the treated firm and its control if the new connections are in the top half in terms of the cosine similarity score between the treated firm and its new connections, and some new connections are in the same SIC-3 industry as the treated firm
Geographical Distance	Geographical distance between the zip codes (<i>addzip</i>) of the treated firm and its newly connected peer. If a treated firm is incrementally connected to multiple peer firms, it takes the value of the smallest distance
Close Distance	A dummy that equals one for the time series of both the treated firm and its control if the new connections are in the bottom half in terms of Geographical Distance between the treated firm and its new connections
HHI	The Herfindahl-Hirschman index of the text-based industry that the treated firm is in (Hoberg and Phillips, 2016)
Top HHI	A dummy that equals one for the time series of both the treated firm and its control if the treated firm is in the top half in terms of HHI among all treated firms treated in the same year
Returns to Scale	The estimated returns to scale of the industry that the treated firm is in. Following Dong et al. (2019), we estimate a two-factor Cobb-Douglas production function for each SIC-2 industry using data of the year 1999 and OLS regressions. We proxy for the firm's output by its sales (<i>sale</i>), the firm's labor by the number of its employees (<i>emp</i>), and the firm's capital by its property, plant, and equipment (<i>ppent</i>). We then add up the coefficients for the proxies for labor and capital, which is our measure of an industry's returns to scale

Table A1: List of variables in the main test (continued)

Panel C: Sorting variables (continued)

Top Returns to Scale	A dummy that equals one for the time series of both the treated firm and its control if the industry of the treated firm is in the top half in terms of Returns to Scale
----------------------	--

Panel D: Other variables

GGL_{linear}	<p>The firm-pair-year level measure of common ownership developed in Gilje et al. (2020), which is defined as</p> $GGL_{linear}(A, B) = \sum_{i=1}^I \alpha_{i,A} g(\beta_{i,A}) \alpha_{i,B},$ <p>where $\alpha_{i,A}$ is the fraction of firm A's shares held by investor i, $\alpha_{i,B}$ is the fraction of firm B's shares held by investor i, and $\beta_{i,A}$ is the weight of firm A in investor i's portfolio. Function g describes how the likelihood of an investor being attentive is increasing in how important a stock is in this investor's portfolio. It is assumed to take a linear form</p>
GGL_{fitted}	A version of common ownership measure developed in Gilje et al. (2020) that uses a non-parametric fitted attention function estimated with voting data
GGL_{full_attn}	A version of common ownership measure developed in Gilje et al. (2020) that assumes full attention, i.e., $g = 1$
$\Delta(CommonOwnership)$	<p>The change in the within-industry common ownership, i.e., the mean common ownership between a firm and all its Hoberg-Phillips product market peers from $\tau = -3, -2, -1$ to $\tau = 0, 1, 2, 3$. For each treated firm, we calculate the average common ownership measure between the firm and all of its Hoberg-Phillips product market peers. We do it separately for each year from $\tau = -3$ to $\tau = 3$. Then we take a prior-event average using $\tau = -3, -2, -1$, and a post-event average using $\tau = 0, 1, 2, 3$, and take the post-minus-prior difference. We arrive at a constant for each time series of length 7 (from $\tau = -3$ to $+3$). We do the same calculation for each control firm around the treatment year of the treated firm it is matched to. Finally, we scale this measure by its sample standard deviation</p>

Table A2: Characteristics of directors involved in board connections

	Connected Directors			Other Directors		
	Mean	SD	N	Mean	SD	N
Age	58.6	8.3	6,999	59.1	9.4	39,555
Is Female	0.12		6,999	0.10		39,555

Note: This table reports results from the following regression using the sample of all events,

$$\begin{aligned}
Y_{i,j,c,t} &= \alpha_1 \times Post_{c,t} + \alpha_2 \times DirectTreated_{i,c} + \alpha_3 \times IndirectTreated_{i,c} \\
&+ \beta_1 \times DirectTreated_{i,c} \times Post_{c,t} + \beta_2 \times IndirectTreated_{i,c} \times Post_{c,t} + \theta_i + \theta_{j,t} + e_{i,j,c,t}.
\end{aligned}$$

Column (1) uses $\ln(Sales)$, the natural logarithm of total sales (*sale*) as the outcome variable. Column (2) uses the logarithm of the cost of good sold (*cogs*). Column (3) uses the logarithm of selling, general and administrative costs (*xsga*). Column (4) uses the markup calculated using the production approach, following De Loecker et al. (2020). Column (5) uses the markup calculated using the cost share approach and adjusting for intangible capital, following Peters and Taylor (2017) and Ayyagari et al. (2023). Column (6) uses the logarithm of assets (*at*). Column (7) uses the logarithm of capital expenditure (*capex*). Column (8) uses the logarithm of R&D expenditure (*xrd*). Column (9) uses Tobin's Q. All outcome variables are winsorized at their 1% and 99% percentiles. T-stats are in parentheses. Standard errors are clustered at the firm level. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$.

Table A4: Double-difference regressions, using the non-focal-firm initiated subset of events, requiring that the intermediate firm is not a product market peer of the treated firm

Note: This table reports results from the following regression using the subset of events that are non-focal-firm initiated,

$$Y_{i,j,c,t} = \alpha_1 \times Post_{c,t} + \alpha_2 \times ExogenousTreated_{i,c} + \beta_1 \times ExogenousTreated_{i,c} \times Post_{c,t} + \theta_i + \theta_{j,t} + e_{i,j,c,t}.$$

Here $Post_{c,t}$ is one for both treated and control firms for the years $\tau = 0, 1, 2,$ and $3,$ where $\tau = 0$ is the treatment year. Coefficient on $Post_{c,t}$ is the estimated difference between prior and post for the control firm. $ExogenousTreated_{i,c} \times Post_{c,t}$ is the double difference term, the coefficient of which is the estimated effects of non-focal-firm initiated new board connection with peer firms. θ_i are firm fixed effects. $\theta_{j,t}$ are industry times year fixed effects based on the Fama-French 48-industry classification. T-stats are in parentheses. We omit coefficients of $ExogenousTreated_{i,c}$ from the table. Standard errors are clustered at the firm level. *** $p < 0.01,$ ** $p < 0.05,$ * $p < 0.1.$

Note: This table report coefficients for the regression in Table 5 if alternative matching schemes are used. Panel A (B) uses a matching scheme that retains two (three) controls for each treated event. Panel C uses a matching scheme that additionally requires an exact match on the number of new appointments to the board during the event year. Panel D uses a matching scheme that matches on operating margin instead of gross margin. Panel E (F; G; H; I) uses a matching scheme that additionally matches on operating margin (sales growth; ROA; R&D to Assets; CAPEX to Assets). Panel J matches on all variables when R&D to Assets is non-missing for the treated firm and on all variables but R&D to Assets when it is missing. Panel K uses a matching scheme that additionally requires the control firm being never treated from $\tau = -3$ to $+3$. Panel L uses a matching scheme that additionally requires the control firm being never treated before or during $[-3, 3]$.

Table A12: Robustness to alternative fixed effects

	Gross Margin	Operating Margin	ROA
<i>Panel A: SIC-3 × Year FE and Firm FE</i>			
DirectTreated × Post	0.008** (2.54)	0.015*** (4.03)	0.010*** (4.08)
IndirectTreated × Post	0.004* (1.67)	0.008*** (3.32)	0.008*** (4.31)
<i>Panel B: FIC-200 × Year FE and Firm FE</i>			
DirectTreated × Post	0.008*** (2.58)	0.013*** (3.77)	0.008*** (3.16)
IndirectTreated × Post	0.003 (1.11)	0.006*** (2.79)	0.006*** (3.45)
<i>Panel C: FF-48 × Year FE and Firm-Cohort FE</i>			
DirectTreated × Post	0.008** (2.29)	0.014*** (3.84)	0.009*** (3.41)
IndirectTreated × Post	0.004* (1.81)	0.008*** (3.38)	0.006*** (3.74)

Note: This table report coefficients for the regression in Table 5 if alternative fixed effects are used. Regressions in Panel A use SIC-3 industry times year fixed effects and firm fixed effects. Regressions in Panel B use FIC-200 industry times year fixed effects and firm fixed effects. FIC-200 industry classification is provided in the Hoberg-Phillips Data Library. Regressions in Panel C use Fama-French 48-industry times year fixed effects and firm-cohort fixed effects.

Table A13: Robustness to alternative clustering

	(1)	(2)	(3)
	Gross Margin	Operating Margin	ROA

DirectTreated \times Post	0.008** (2.34)	0.014*** (3.60)	0.009*** (3.45)
IndirectTreated \times Post	0.004* (1.95)	0.008*** (3.55)	0.007*** (3.99)
Observations	68,690	68,534	68,602
Firm FE	Yes	Yes	Yes
FF48 \times Year FE	Yes	Yes	Yes
Clustering	Unit	Unit	Unit
# of Matched Controls	1	1	1
Within R-squared	0.001	0.001	0.002

Note: This table report coefficients for the regression in Table 5 if alternative clustering of standard errors is used. We cluster the standard errors at the unit level, which we define to be all observations of a connected firm-pair for treated firms and all observations of a single firm for control firms. This method of clustering accounts for the possibility that the outcome variables of connected firm-pairs can be highly positively correlated and treating them as separate units can lead to an overestimation of the power of the tests.

Table A14: Robustness to using alternative industry classification

	Gross Margin	Operating Margin	ROA
<i>Panel A: Using FactSet to identify peer firms</i>

IndirectTreated \times Post	0.003* (1.80)	0.006*** (2.91)	0.006*** (3.62)
Observations	72,090	71,947	71,995

Note: This table report coefficients for the regression in Table 5 if alternative industry classifications are used in the definition of product market peers when constructing events of board connections. Panel A uses the competitors disclosed by firms and recorded in FactSet Supply Chain Relationships database. Panel B uses SIC-3 industry. Panel C uses SIC-4 industry. Panel D uses GICS 6-digit industry. Panel E uses GICS 8-digit industry.

Table A15: Robustness to controlling for connections between customer-supplier firms

	(1) Gross Margin	(2) Operating Margin	(3) ROA
NonCusSupTreated \times Post	0.005** (2.40)	0.010*** (4.27)	0.007*** (4.44)
CusSupTreated \times Post	0.004 (0.68)	0.018* (1.87)	0.016*** (2.83)
Observations	68,690	68,534	68,602
Firm FE	Yes	Yes	Yes
FF48 \times Year FE	Yes	Yes	Yes
Clustering	Firm	Firm	Firm
# of Matched Controls	1	1	1
Within R-squared	0.001	0.001	0.002

Note: This table reports results from the following regression

$$\begin{aligned}
Y_{i,j,c,t} &= \alpha_1 \times Post_{c,t} + \alpha_2 \times NonCusSupTreated_{i,c} + \alpha_3 \times CusSupTreated_{i,c} \\
&+ \beta_1 \times NonCusSupTreated_{i,c} \times Post_{c,t} + \beta_2 \times CusSupTreated_{i,c} \times Post_{c,t} \\
&+ \theta_i + \theta_{j,t} + e_{i,j,c,t}.
\end{aligned}$$

Here $Post_{c,t}$ is one for both treated and control firms for the years $\tau = 0, 1, 2,$ and $3,$ where $\tau = 0$ is the treatment year. Coefficient on $Post_{c,t}$ is the estimated difference between prior and post for the control firm. In this regression we pool events of new direct and indirect connections together. $NonCusSupTreated_{i,c}$ equals one for the time series of a firm experiencing new direct or indirect connections to a product market peer that is not its customer or supplier firm. $CusSupTreated_{i,c}$ equals one for the time series of a firm experiencing new direct or indirect connections to a product market peer that is a customer or supplier firm of its. θ_i are firm fixed effects. $\theta_{j,t}$ are industry times year fixed effects based on the Fama-French 48-industry classification. We omit coefficients of $Post_{c,t}, NonCusSupTreated_{i,c},$ and $CusSupTreated_{i,c}$ from the table. T-stats are in parentheses. Standard errors are clustered at the firm level. *** $p < 0.01,$ ** $p < 0.05,$ * $p < 0.1.$

Table A16: Robustness to controlling for connections between firms that form joint ventures or strategic alliance

	(1)	(2)	(3)
	Gross Margin	Operating Margin	ROA
NonAllianceTreated \times Post	0.005** (2.36)	0.010*** (4.37)	0.008*** (4.70)
AllianceTreated \times Post	0.004 (0.70)	0.004 (0.57)	-0.002 (-0.51)
Observations	68,690	68,534	68,602
Firm FE	Yes	Yes	Yes
FF48 \times Year FE	Yes	Yes	Yes
Clustering	Firm	Firm	Firm
# of Matched Controls	1	1	1

Note: This table reports results from the following regression

$$\begin{aligned}
 Y_{i,j,c,t} = & \alpha_1 \times Post_{c,t} + \alpha_2 \times NonAllianceTreated_{i,c} + \alpha_3 \times AllianceTreated_{i,c} \\
 & + \beta_1 \times NonAllianceTreated_{i,c} \times Post_{c,t} + \beta_2 \times AllianceTreated_{i,c} \times Post_{c,t} \\
 & + \theta_i + \theta_{j,t} + e_{i,j,c,t}.
 \end{aligned}$$

Here $Post_{c,t}$ is one for both treated and control firms for the years $\tau = 0, 1, 2,$ and $3,$ where $\tau = 0$ is the treatment year. Coefficient on $Post_{c,t}$ is the estimated difference between prior and post for the control firm. In this regression we pool events of new direct and indirect connections together. $NonAllianceTreated_{i,c}$ equals one for the time series of a firm experiencing new direct or indirect connections to a product market peer that it never formed strategic alliance or started joint venture with during the sample period. $AllianceTreated_{i,c}$ equals one for the time series of a firm experiencing new direct or indirect connections to a product market peer that it ever formed strategic alliance or started joint venture with during the sample period. θ_i are firm fixed effects. $\theta_{j,t}$ are industry times year fixed effects based on the Fama-French 48-industry classification. We omit coefficients of $Post_{c,t}, NonAllianceTreated_{i,c},$ and $AllianceTreated_{i,c}$ from the table. T-stats are in parentheses. Standard errors are clustered at the firm level. *** $p < 0.01,$ ** $p < 0.05,$ * $p < 0.1.$

Table A17: Director network and detected cartel cases

	(1) Prob. of active detected cartel (%)	(2) Prob. of active detected cartel (%)
Degree of separation = 0	0.058*** (3.22)	0.043** (2.39)
Degree of separation = 1	0.060*** (9.07)	0.053*** (8.41)
Degree of separation = 2	0.017*** (12.21)	0.014*** (10.93)
Degree of separation = 3	0.003*** (10.30)	0.002*** (7.89)
Cosine similarity score		0.285*** (10.91)
Is H-P peer		0.036*** (5.73)
Observations	53,893,933	53,893,933
Year FE	No	Yes
Firm-pair FE	No	No

Note: This table reports results from the following Probit regression

$$\begin{aligned} \mathbb{1}(\text{Having an active detected cartel})_{i,j,t} &= \sum_{m=0}^3 \beta_m \times \mathbb{1}(\text{Degree of separation is } m)_{i,j,t} \\ &+ \text{Control}_{i,j,t} + \theta_t + e_{i,j,t}. \end{aligned}$$

using the sample of firm-pairs with the degree of separation in the director network less than or equal to 4. Firm-pairs with a degree of separation of 4 serve as the omitted category. T-stats are in parentheses. Standard errors are clustered at the firm-pair level. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$.

Figure A1: Distribution of new board connections over time

Note: This figure plots the number of new direct and indirect board connections in each year over our sample period of 1999-2018.

Figure A2: Plots of the dynamics of the difference between firms subject to spillover effects and control firms

Panel A1: Gross margin, direct

Panel B1: Operating margin, direct

Panel C1: ROA, direct

Panel A2: Gross margin, indirect

Panel B2: Operating margin, indirect

Panel C2: ROA, indirect

Note: This figure plots coefficients from the following regression,

$$\begin{aligned}
Y_{i,j,c,t} &= \alpha_1 \times DirectSpillover_{i,c} + \alpha_2 \times IndirectSpillover_{i,c} \\
&+ \sum_{s=-3}^{-2} \beta_s \times \mathbb{1}(\tau = s)_{c,t} + \sum_{s=0}^3 \beta_s \times \mathbb{1}(\tau = s)_{c,t} \\
&+ DirectSpillover_{i,c} \times \left(\sum_{s=-3}^{-2} \gamma_s \times \mathbb{1}(\tau = s)_{c,t} + \sum_{s=0}^3 \gamma_s \times \mathbb{1}(\tau = s)_{c,t} \right) \\
&+ IndirectSpillover_{i,c} \times \left(\sum_{s=-3}^{-2} \delta_s \times \mathbb{1}(\tau = s)_{c,t} + \sum_{s=0}^3 \delta_s \times \mathbb{1}(\tau = s)_{c,t} \right) \\
&+ \theta_i + \theta_{j,t} + e_{i,j,c,t}.
\end{aligned}$$

Here t represents the calendar year and τ represents the year relative to the treatment. $\mathbb{1}(\tau = s)_{c,t}$ is a dummy variable that is equal to one if the observation is $-s$ years before the treatment (for $s = -3, -2$) or if the observation is s years after the treatment (for $s = 0, 1, 2, 3$). We omit the dummy variables for the year prior to the event, i.e., $\tau = -1$, which forms the baseline year. Thus all the effects we document are relative to this year. The estimates of γ_s and δ_s capture the difference in outcome variables between firms subject to spillover effects and control firms of year s relative to their differences in the baseline year. Standard errors are clustered at the firm level.

Figure A3: Director network and detected cartel cases

Note: This figure plots the probability of a firm-pair in a certain year being in an active detected cartel case, conditional on each level of degree of separation between the firm-pair in the director network.

IA.2 Definition of the non-focal-firm initiated subset of events

In this paper, we refer to the new board connections as both the scenarios of a firm appointing new directors, and existing directors taking on new roles at other firms. These changes on the board of the focal firm could be related to certain future prospects of this focal firm. Our non-focal-firm initiated subset of events aims to avoid such changes that can be directly linked to firm future prospects. In this section, we describe how we define and operationalize the non-focal-firm initiated subset of events.

We consider board connections that occur solely due to changes outside of the board of the focal firm. To identify this subset of events, we first identify the complement set of it, which is the set of events that occur at least partly due to changes on the board of the focal firm. Note that by definition new direct connections take place because of changes to the board of the focal firm, so our non-focal-firm initiated events only consider (a subset of) new indirect connections.

In particular, we consider that an event is *not* a non-focal-firm initiated one, if either:

1. the appointment of new directors to the focal firm triggers new connections between the focal firm and its product market peers, and/or
2. new board positions taken by existing directors in the focal firm triggers new connections between the focal firm and its product market peers.

Taking out these *not* non-focal-firm initiated events from the set of all events, we get the subset of events that we deem to be non-focal-firm initiated. These events occur solely due to changes on the board of a third intermediate firm or a product market peer, and not due to any changes on the board of the focal firm.

We further decompose how the sample of all new connections relates to non-focal-firm initiated events with the following Venn diagram:

Figure A4: Definition of the non-focal-firm initiated subset of events

	All events of new connections	5,578
■	Some new connections result from new appointment of directors to the focal firm	$1,364 + 296 = 1,660$
■	Some new connections result from existing directors on the focal firm's board taking on directorship elsewhere	$1,804 + 296 = 2,100$
■	New connections purely result from changes on boards of other firms (The non-focal-firm initiated subset of events)	2,114

IA.3 Director network and detected cartels

We obtain information on convicted cartels from the Private International Cartels Database (Connor, 2020). We restrict the sample to firms headquartered in the US, and hand-match those firms to the universe of firms we described in Section 2. Equipped with these cartels cases, we construct a firm-pair-year level indicator of whether two firms are in an active detected cartel in a certain year. We also construct the degree of separation of each firm-pair in the network, which is the minimum number of intermediate firms that can connect these two firms together. Hence, two directly connected firms have a degree of separation of zero and two indirectly connected firms have a degree of separation of one. We exclude firm-pairs that are unconnected in the director network or connected but with a degree of separation above four.

We first plot the probability of a firm-pair having an active detected cartel in a certain

year, conditional on the degree of separation of these two firms in the director network. We find that while this probability is around 0.06% for firm-pairs with a degree of separation of zero or one, it becomes 0.017% for firm-pairs with a degree of separation of two, and diminishes to near zero as the degree of separation further increases.

Next, we estimate the following probit model on this sample:

$$\begin{aligned} \text{Prob}(\text{Having an active detected cartel})_{i,j,t} &= \sum_{m=0}^3 \beta_m \times \mathbb{1}(\text{Degree of separation is } m)_{i,j,t} \\ &+ \text{Control}_{i,j,t} + \theta_t + e_{i,j,t}, \end{aligned}$$

where i and j are indexes for the pair firm i and firm j and t is the index for the calendar year. We report the results in Internet Appendix Table A17. Column (1) reports the probability of having an active detected cartel, with firm-pairs of degree of separation of four being the baseline group. As firms closer in the director network might have more similar businesses, which can be a confounding factor that affects the tendency for anti-competitive practices, in column (2) we also control for the cosine similarity of two firms' business descriptions as well as an indicator for whether the two firms are in the same Hoberg-Phillips industry. For both specifications, the associative relationship between the degree of separation in the director network and the probability of having an active cartel holds.

IA.4 Matching Nielsen Retail Scanner Data to BoardEx

We start by matching the Nielsen Retail Scanner Data (Nielsen) to producers in the GS1 Company Database. Universal Product Code (UPC) is the unit at which prices are recorded in Nielsen Retail Scanner Data, and the first 6-9 digits of it is a prefix that can identify the producer of the product. Each UPC-prefix corresponds to a unique producer. The GS1 Company Database records the name of each producer and the prefixes it owns. Following Baker et al. (2023), we start from the set of all UPCs in the Nielsen Retail Scanner Data and obtain their first 6-9 digits, which are our candidate UPC-prefixes. Then we search for these UPC-prefixes in the GS1 Company Database. While the length of a UPC-prefix can vary between 6 to 9, by the rule of its assignment, there will not be a longer UPC-prefix

that contains a shorter UPC-prefix as its first many digits (Baker et al., 2023). Hence, if one of the four candidate prefixes for a UPC belong to a producer in the GS1 Company Database, its producer can be uniquely pinned down. Out of 6,087,712 UPCs, we are able to find producer information for 4,695,783 of them.

Next, we match the producers in the GS1 Company Database to BoardEx. As there is no common identifier among these two databases, we match by the name string. First, we perform an exact match of firm names in the GS1 Company Database to firm names in BoardEx.²⁵ Second, we use WRDS Company Subsidiary Data to identify subsidiaries of firms in BoardEx and then we do an exact match of firm names in the GS1 Company Database that are still not matched in the prior step to the names of subsidiaries of firms in BoardEx. Third, for the remaining unmatched firm names in the GS1 Company Database, we conduct a fuzzy match between them and firms in BoardEx. We manually check the results from the fuzzy match and make sure we only retain correct matches. Finally, we manually check the top 1,000 UPC-prefixes with the most sales and see if they can be matched to a firm in BoardEx. In this step, we employ Google search and also the location information that is provided in the GS1 Company Database.

We are able to match 2,715,025 UPCs to a firm in BoardEx, which account for 44.6% of all UPCs and 63.4% of the total sales in the Nielsen Retail Scanner Data.

²⁵We clean the firm names by dropping suffixes such as "Co", "Inc", and "Corp" and removing special characters before matching by the name string.
